Close to one of the mounds, or the boundary between the two farms, had stood two stelae. One of these (Fig. 17.1a) was removed some years ago, and set up in front of the house of Sr. Guillermo Mohr, owner of the Finca San Isidro Piedra Parada. It is

1.36 m high from the bottom of the sculptured area, and is slightly tapering, with a maximum width of 72 cm and depth of 45 cm.

Only the front is sculptured. This shows an individual with head and feet in profile, but body partially turned to the front. The personage wears over the lower part of the face a snout-like mask that might represent the snout of Ehecatl or possibly the exaggerated muzzle of a jaguar. However, the rather bulbous nose above the mask is human, not animal. The right hand is prominently displayed with forefinger pointed forward in what appears to be a formal gesture. A large spiral dominates the head-dress, and there is a grotesque head of a monster on the left shoulder. A short vertical panel reveals the faint outlines of glyphs, and below this there is an elaborate representation of what appears to be a serpent. Above the individual is a complex arrangement which is almost certainly a celestial monster symbolizing the heavens. The figure stands on a low pedestal with a simple geometric pattern that spans the base of the stela.

The general style is reminiscent of that of Izapa, Chiapas, which is distant only some 60 km in a direct line, but there are also parallels with the sculptural art of the La Venta culture. The treatment of the heads of monsters is particularly close to that found at Izapa. The pedestal on which the figure stands recalls that of the Piedra Herrera at El Baul, Escuintla, the obelisk from Alvarado, Veracruz, and a band which occurs at Izapa not at the bottom, but at the top of a stela. The formal display of the hand in an act of

17.1. Stelae from southeastern Quezaltenango: (a) Stela 1, San Isidro Parada; (b) Stela 2, Santa Margarita.

gesture, the Eecatl-like mask, and the prominent, rather squarish anklets are features shared with La Venta art. The spiral of the headdress is somewhat like that found in Maya sculptures of the Middle and Great Periods, particularly at Yaxchilan (Lintels 3, 7, 33, and Stela 22), but in view of the prevalence of spirals in Middle American art, this resemblance probably has no chronological value.

Stela 2 stood close to Stela 1 but on the Santa Margarita side of the boundary. Because it was the object of offerings and worship by Indians working in the neighborhood, Sr. Zacarias Saenz, owner of the farm, had it interred, leaving exposed only the top few inches. So far as I could gather it was not moved

from its original location. Sr. Saenz graciously permitted us to excavate this monument to photograph it. After that it was again covered with earth.

This stela (Fig. 17.1b) is 2.12 m from top to bottom of the sculptured area, and 1.43 m across at the point of maximum width. It has a most unusual scalloped outline. Only the front is carved. The top is occupied by an extremely involved design in which spirals predominate. The subject is difficult to elucidate but may represent a celestial monster symbolizing the sky. Beneath the center of this is a vertical glyph panel with a width of 20 cm including the raised edges. The inscription opens with a glyph, 18 cm high, which is pretty clearly the Initial Series

Introducing Glyph of Maya inscriptions save that it lacks the variable element denoting the patron of the month of the Initial Series, and its flanking comb-like elements.

Nearly 5 cm beneath this is a numerical dot close to the left edge of the panel, and a numerical bar immediately below it. The surface above the right edge of the bar had flaked off, but for reasons of symmetry there must once have been a second dot there. It appeared that there had never been a third and central dot, although because of the condition of the stone, that possibility cannot entirely be eliminated. A reading of seven for the whole number is far and away the best. The area below this coefficient is eroded and partly flaked except close to the left edge, where it is plain. There are, however, traces of what may have been a numerical dot on the left of the panel 10.5 cm below the bottom of the bar. The rest of the inscription is entirely gone.

From the little that remains it is clear that the inscription is one of those numbers unattached to glyphs which have been reported from southern Veracruz, Chiapas, and Escuintla. Not far from Finca Santa Margarita, Walter Lehmann found on the Finca El Rosario Bola de Oro the monument known as La Piedra Schlubach, which he reports opens with the number seven with no glyph attached. The rest of the inscription was too badly damaged to yield more epigraphic data.

In the presence of an Initial Series Introducing Glyph, Stela 2, Santa Margarita, resembles Stela 1, Pestac, although the latter shows the variable element denoting the patron deity of the month.

The glyph panel was flanked by what appear to have been individuals or gods. That on the observer's left is partially preserved. This shows a personage who appears to wear a beaked mask over the lower part of his face and has an elaborate headdress which might represent a feathered serpent. The supposed mask is not properly placed if it is meant to cover the man's face. Viewed upside down it might pass for the head of the serpent, which, in that case, would entirely hide the man's head.

A feature of the individual on this stela, as well as that on Stela 1, is a chain which hangs diagonally to the rear from the belt. This feature is also found on the Leyden Plate, but occurs, too, on Maya sculptures dating from the middle of Cycle 9. There is, moreover, a vague resemblance between the headdress on Stela 2 and part of the headdress of the individual on the front of the Leyden Plate. However, the presentation in general and the scrollwork in particular are definitely in Izapa tradition.

About a kilometer from the main group and close to a small stream is a large boulder with a human

figure carved in low relief on one of its surfaces. The individual, like those on the two stelae, wears a mask, which in this case has as its main feature a long pendulous nose (Fig. 17.2a). He rests on one knee in an attitude in which ball-game players are often depicted. The right hand may be encased in a glove such as ball-game players used. The left hand grasps what appears to be a curved blade. The design shows considerable skill and lacks the awkwardness apparent in the figures on the two stelae. Curved blades, such as this figure holds, are rather rare. One may be seen on Stela 1, Comitan (10.2.5.0.0), on a fresco showing a human sacrifice from the Temple of the Warriors, Chichen Itza, and, in slightly modified form, on a stela at Izapa. The general presentation again has obviously been affected by the same influences responsible for certain features of the styles of Izapa and La Venta.

At the hacienda of San Isidro Piedra Parada there is also a zoomorph representing a crouching Jaguar with legs in low relief on the sides. This sculpture is 1.52 m long, 96 cm wide, and 52 cm high. Features are in low relief with straight lines and fret-like designs dominant, each eye being represented by a circle enclosed in three sides of a rectangle, the bottom line being absent. There is a bowl-like offering in the center of the back. The sculpture is somewhat reminiscent of a Jaguar altar before a stela at Izapa and a zoomorph at San Andres Osuna, Escuintla. There is also at the hacienda a drum-like altar of considerable diameter but undecorated (Fig. 17.2f).

An intricate curvilinear pattern on a boulder on the Finca San Francisco Miramar, near Coatepeque, hints that a careful search might reveal other sites in southwestern Guatemala with sculptures influenced by the Izapa style (Fig. 17.2g).

There are various other sculptures of a very different style on the San Isidro Piedra Parada farm. One (height 1.63 m.) is a very crude representation of a seated person or animal (Fig. 17.2b). An equally crude sculpture (height 93 cm) is at the Hacienda Santa Margarita, but the lower half is missing. The individual wears a necklace of tubular beads (Fig. 17.2c).

Two sculptures in the round at San Isidro Piedra Parada show a kneeling posture. The head is missing from the first (present height 82 cm) which represents a person with his hands tied behind his back with a sash, and who is naked except for a three-pronged loincloth (Fig. 17.2d, e). The second sculpture shows features, such as round, sunken eyes, a certain prognathism and marked supraorbital ridges meeting above the bridge of the nose, which indicate that the subject is a monkey or a person wearing a

17.2. monkey, mask. The hands rest in front of the stomach (Fig. 17.2f).

At the Hacienda Santa Margarita a fragmentary sculpture (42 cm high) is shaped as the trunk of a person with hands supporting a distended stomach (Fig. 17.3a). A similar motif was found at the Finca Buenos Aires (formerly Finca El Recuerdo), which lies only a few kilometers northwest of San Isidro Piedra Parada. The headless figure (45 cm high) has vestigial legs, and the hands rest on an enormously distended stomach (Fig. 17.2c). A third sculpture of an individual with very enlarged paunch was seen at Finca Moca, Solola, due south of Lake Atitlán.

A very few sherds were observed in excavating Stela 2, and with one exception all were too small to yield any information. The exception was a sherd of plumbate ware from the redeposited fill in front of the stela, but because of the conditions under

which it was found, it has no chronological value. The small archaeological collection of Sr. Enrique Montes at Finca Buenos Aires included a plumbate jar with a fine representation of what appears to be a turkey in relief on the front, two or three frog heads of plumbate, presumably from frog effigy vessels, and one complete jar of this form. This last was rather badly weathered. It appeared to be an imitation of this well-known plumbate form in another ware but might have been of misfired plumbate. Other plumbate vessels have been found on fincas near Colomba.

The Montes collection also included a number of feet of vessels in animal or human form. One was shaped as the flat head of a snake, and had been attached to a bowl with a slip of specular hematite red. A second support probably represents a foot, and is covered with a brownish red slip (Fig. 17.3b,

17.3. Stonework and Pottery: (a) headless figure with distended belly, Santa Margarita; (b) pottery feet of vessels, Buenos Aires; (c) headless figure and metate, Buenos Aires; (d) pottery spindle whorls, Buenos Aires; (e) pottery heads, Buenos Aires; (f) stonework, Buenos Aires; (g) "Palma"-like head, La Concepcion; (h) metate, El Paraiso; (i) profile view of g.

right). Another shows the wrinkled face of an old man (Fig. 17.3e, center), and two represent monkeys heads (Fig. 17.3b, left). In an article in *Los Mayas Antiguos* Robert Wauchope has shown that effigy supports are late and occur on the same horizon as do plumbate effigy vessels.

There were, too, in the Montes collection several pottery spindle whorls with incised (and in one case perhaps also stamped) designs (Fig. 17.3d). Excavations at San Jose, British Honduras, and elsewhere indicate that purposely manufactured spindle whorls of clay are a late innovation. There were also in the Montes collection some crude heads, presumably from incense burners but perhaps once set on the rims of vessel's (Fig. 17.3e).

Smaller stonework at Finca Buenos Aires included a small seated figure, headless, and with hands resting on the stomach (Fig. 17.3f), a complete metate (corn grinder) of rectangular trough type and with two short feet at one end (Fig. 17.3c). This latter seems to represent a common local type, since several metates in the collection of Lic. Vitalino Robles, which are of the same shape and similarly supported by two feet at one end, come from Finca El Paraiso in the neighborhood of Colimba.

A foot, probably broken from a metate, in the Montes collection is in the shape of a long-snouted animal head (Fig. 17.3f, right). There is also in this collection a spherical stone perforated for holding (Fig. 17.3f). There are other examples of such stones in the Robles collection which were found on the Finca El Paraiso and the nearby Rosario Tinhuinlinhuitz. They resemble closely stones from central Veracruz identified by Fewkes as sling stones. Yet Another stone in the Montes collection is ring-shaped. It is of lava, and of a type sometimes known as clubheads (Fig. 17.3f).

The Montes collection, all of which comes from the small mound where the farm buildings were erected, also includes two bark beaters. Both are rectangular and with a channel running around three sides. One has both faces scored with parallel grooves; the other has only one surface thus treated.

Most, if not all, of this collection from Finca Buenos Aires appears to be late, but naturally there is no evidence that it is of the same age as the best sculptures from San Isidro Piedra Parada and Santa Margarita.

This area produced some very fine examples of skill in smaller stonework. In the Robles collection there is a magnificent metate from Finca El Paraiso, the front support of which is in the form of a superbly modeled human head, beneath or in the jaws of a long-snouted reptile. There is a certain

Totonac feeling in the treatment of the head (Fig. 17.3h). In the same collection, but from the nearby Finca La Concepcion, is a very forceful monkey head of the type called "palma," which is also reminiscent of pieces from central Veracruz and adjacent territory (Fig. 17.3g, i). Recent evidence of Totonac Maya contacts would tend to place these two, pieces on a pre-plumbate horizon.

The area under discussion was perhaps Mam-speaking in the 16th century. According to the chronicler of Friar Alonso Ponce's travels, the town of Tlilapa, which was the last of the Province of Soconusco and which was nearly three leagues from where the Tonalá-Guatemala road crossed the Tlilapa river (the boundary between Soconusco and Guatemala), spoke a language different from that of Tapachula, and, by inference, not of the Achi (Quiche, Cakchiquel, and Zutuhil) group. It is highly probable that this was Mam, a language reported to have been spoken in parts of adjacent Zapotitlan. However, the chronicler adds that these Indians were recent arrivals, who used to visit this area to obtain cacao but who took up permanent residence there after the native population had been exterminated by disease. From other sources we know that the population of Soconusco declined very rapidly in the period between the Spanish conquest and Friar Ponce's visit. It is therefore possible that this southeastern corner of Quezaltenango was once inhabited by Tapachulteco.

The Tapachultec spoke a language which is generally grouped with Mixe-Zoque, and in their territory are situated the ruins of Izapa. It is, therefore, tempting to assign the San Isidro Piedra Parada and Santa Margarita stelae to a former Tapachulteca occupation. Nevertheless, one must bear in mind that boundaries of art styles and languages do not necessarily coincide, and, furthermore, that the San Isidro stela has a clearly Maya Initial Series Introducing Glyph.

In discussing the use of bars and dots without accompanying glyphs in *Dating of Certain Inscriptions of Non-Maya Origin I* (1941) suggested that the 400-day year of the Cakchiquel might have been borrowed from southern Veracruz, although at that time no evidence in favor of the idea was advanced.

Recently I have run across a statement indicating that a 400-day count did in fact exist on the coast of the Gulf of Mexico. Peter Martyr, in decade 4, chapter 8, of his *The Historie of the West Indies*, says, "In their language they call the Sunne Tonatico: yet somewhere it is otherwise, where yet without shew of reason they divide the yeere into 20 moneths, and include the moneths also into 20 days."

Peter Martyr wrote the fourth decade of his memorable book in 1520, before Cortes had despatched his second letter, and before the news of the advance on Tlaxcala and Tenochtitlan had reached Europe. On the other hand, Cortes' first letter, the gold, hieroglyphic books, and other presents had reached Europe. Peter Martyr had seen the Indians who had been sent to Spain with them, and had talked with various members of the original expedition. His narrative contains many details not found elsewhere, and these presumably came from verbal information, perhaps supplemented by data in the missing first letter of Cortes.

The region where this calendar of 20 months, each of 20 days, was used must have been in Yucatan, Campeche, Tabasco, or Veracruz, since those were the only parts of what is now Mexico concerning which there was any information at the time Peter Martyr wrote his fourth decade. We can eliminate Yucatan, Campeche, and northeastern Tabasco since these were areas where the lowland Maya calendar was in use. Unless Martyr's statement refers to the country between Honduras and Panama, which is hardly likely, the conclusion is unavoidable that

a 400-day period was in use somewhere in central or southern Veracruz or contiguous Tabasco. There are also vague hints at the use of a vigesimal system for counting years among the Totonac. Spinden has called attention to Torquemada's statement that every Totonac ruler governed 80 years, and the total period they ruled was 800 years. In the *Papeles de Nueva España* (Paso y Troncoso 1905) the statement is made two or three times that Xonotla and dependent Totonac towns were founded 400 years or about 400 years previously. These figures suggest that the Totonac counted in 20-year and 100-year periods, but, of course, in no way indicate whether the years were of 360, 365, or 400 days.

In view of what Peter Martyr says, it is clear that there were at least two areas in which the 140-day year was used. These were somewhere on the Gulf of Mexico and Cakchiquel territory in the southern highlands of Guatemala. Numerical bars and dots unaccompanied by glyphs have been reported from the Gulf of Mexico, Chiapas, and areas in the south and southwest of Guatemala. Whether the somewhat similar distributions of these two traits are significant remains to be seen.

The Initial Series of Stela 14, Piedras Negras, Guatemala, and a Date on Stela 19, Naranjo, Guatemala

J. Eric S. Thompson

The decipherment of the Initial Series of Stela 14, Piedras Negras, has been generally but reluctantly accepted as 9.18.0.3.1 7 Imix 19 Pax principally because the data given in the lunar series appeared to be in agreement with that decipherment. A reconstruction of the difficult Initial Series has to meet the following conditions:

1. The katun coefficient must be 10, 14, 16, or 17 because the eye of the head form is round, the jawbone is prominent, and there is no headdress.
2. The uinal coefficient must be 10, 14, 16, or 17 for the same reasons.
3. The day is 7 Imix, and therefore the kin coefficient must be 1.
4. Glyph G is form 8.
5. The moon age is 26 days. This cannot be six days because of the presence of Glyph D (Thompson 1929).
6. Glyph C appears to record two moons, but Glyph X is of a form found with 4C or 5C.
7. The month sign is enclosed within a cartouche and has a superfix. The coefficient is 19.

The reading 9.18.0.3.1 7 Imix 19 Pax disagrees with conditions 1, 2, 14, and 7, and therefore must be rejected.

Conditions 2, 3, and 4 require that the uinal coefficient be 17, because only uinal coefficients of 8 and 17 can combine with a kin coefficient of 1 to call for Glyph G8. A uinal coefficient of 8 can be eliminated since that head, which represents the maize god, in variably has an eye of almond shape. In fact, one can

make out the loop under the eye and over the nose which is the diagnostic of the heads for 7 and 17.

On the assumption that the cycle coefficient is 9, the only readings in Katuns 10, 14, 16, or 17 that will meet conditions 3 and 4 and produce the required uinal coefficient of 17 are:

A	9.10.9.17.1	7 Imix	19 Mac	? moons	16 days
B	9.14.7.17.1	7 Imix	14 Ceh	4 moons	14 days
C	9.16.6.17.1	7 Imix	19 Uo	5 moons	27 days
D	9.16.19.17.1	7 Imix	19 Kayab	2 moons	11 days
E	9.17.12.17.1	7 Imix	14 Kankin	4 moons	25 days

Dates B and E can be eliminated because the month coefficients do not meet condition 7. Dates A and D can be rejected because their month signs are not enclosed within a cartouche.

Only Date C remains. The moon age of the period of uniformity corresponding to this is 5C, 6E, or 7E. This agrees with the 6E actually recorded and with the form of Glyph X but disagrees with Glyph C. However, as the recorded forms of Glyphs C and X are incompatible, complete agreement is impossible. The approximate moon ages of all five dates are given, and it can be seen that only Dates C and E agree within reasonable limits with the recorded data, but Date E has already been eliminated.

The tun glyph is too eroded to supply a sure check on this reading, but the photograph almost certainly shows a rounded eye and this agrees with its decipherment as 6.

The position which this monument appears to have occupied supports the readings on the assumption that the stela commemorated the date 9.16.10.0.0 1 Ahau 3 Zip. It is one of six stelae in front of Structure O-13, apparently arranged in two rows. Stelae 14 and 16 form the back row; Stelae 13, 17, 18 and 19 are in front. Stela 14 then would commemorate 9.16.10.0.0. Stela 16, which is next to it, records the next hotun-ending, 9.16.15.0.0.0 Stela 13, which is in front of Stela 16, marks the following katun, 9.17.0.0.0. Stela 17, next to the last, is undecipherable, but Stela 18 very probably records the date 9.17.5.0.0. The last monument in the front row, Stela 19, yields no recognizable date. The custom of erecting in the same location several stelae recording consecutive hotun-endings was rather generally followed at Piedras Negras. The new reading makes Stela 14 the start of the sequence before Structure O-13o. Acceptance of the old reading requires a much less logical reconstruction, wherein several stelae were erected in front of the base of the structure, next two were placed on the terrace of the structure, and then Stela 14 was set up in front of the base but in a position in which it was partially obscured by Stela 19.

In presentation and style Stela 14 very closely resembles Stela 11, which was erected at 9.15.0.0.0. Stelae 25 and 6, dedicated at 9.8.15.0.0 and 9.12.15.0.0 respectively, fall into this group, which shows gods seated in niches formed by the bodies of celestial dragons. The decipherment here proposed reduces the interval between Stelae 14 and 11 by 35 or 40 years, thereby accounting more satisfactorily for their marked similarities.

More than a question of correct decipherment of an inscription is involved in advancing a new reading of the Initial Series of Stela 14. Should 9.18.0.3.1 7 Imix 19 Pax be accepted as the correct rendering

of this Initial Series, it would serve as evidence for the theory that the Maya commemorated important events on their recurrence at the end of one or more Calendar Rounds, for the date 7 Imix 19 Pax, at the position 9.12.14.13.1, occurs on three stelae at Piedras Negras. It is known that the Maya commemorated important dates after the lapse of one or more katuns or even at the end of five tuns, but there is little evidence, except for the above reading of the Initial Series of Stela 14, that Calendar Round anniversaries were observed. By casting doubt on this reading, we eliminate one good reason for imputing to the Maya a practice they may not have followed.

On another occasion (Thompson 1935:101–103) I have discussed cases in which a glyph like a tun sign with a lunar superfix is used with month signs, apparently with the meaning of completion. The small number there listed can be augmented by another example. The front of Stela 19, Naranjo, carries the date 9.17.10.0.0 12 Ahau 8 Pax expressed by means of a Period Ending. A panel of glyphs on the right of the main personage opens with a date 9 ?, Yaxkin completed, the glyph for completion being the same as those discussed in the citation. The glyph to which the coefficient of 9 is attached is clearly a day sign because of its position before a month sign and because of the cartouche which encloses it. It appears to contain a head with an infix on the right side such as is found with Eb. It is, therefore, probable that this date is 9 Eb, Yaxkin completed, corresponding to 9.17.6.8.12 9 Eb, Yaxkin completed, corresponding to 9.17.6.8.12 9 Eb, Yaxkin completed (or 0 Mol).

It must be more than coincidence that three of the four known cases of the use of this completion glyph should occur with Yaxkin and the fourth with Mol, the following month.

Representations of Tlalchitonatiuh at Chichen Itza, Yucatan, and at El Baul, Escuintla

J. Eric S. Thompson

The three friezes which gird the pyramid of the Temple of the Warriors at Chichen Itza, Yucatan, repeat with unrelieved monotony the same ritual. Jaguars, eagles, and an unidentified animal offer slightly conical objects to persons in recumbent positions. The animals are in pairs, set back to back, so that each faces a person. The latter, also in pairs, are placed feet to feet, but with their bodies twisted so that each faces outward toward an animal, at which he appears to point a highly ornamented staff or spear. Other sources of information permit of the ready identification of the conical object each animal holds as a heart.

Each individual has a ring around his eye, a bar-shaped nasal rod, and a peculiar headdress of the kind frequently worn by Tlaloc, the Mexican rain god, in codices of the Borgia group. The combination of ring around eye, straight nasal rod, and this peculiar headdress point unmistakably to Tlaloc, yet Tlaloc has no connection with the offerings of human hearts by eagles and jaguars. However, these Tlaloc-like figures have another attribute, a sweeping curved object, set with beads, which issue from behind the back. This has been correctly recognized as hair, on the strength of its identity with objects attached to the heads of figures depicted on frescoes in the same building.

The frescoes reveal that this coiffure was bright yellow and was set with green beads. There is little doubt that it represents artificial hair, for in one case it is attached to the side of the head of a man who otherwise is bald. The wearers are sacrificial victims, prisoners, and warriors engaged in battle.

One would hardly expect Indian warriors normally to wear flaxen hair studded with jade beads. Such a peruke must have ritualistic significance. It is, indeed, the hair arrangement normally worn by Tonatiuh, the Mexican sun god, and occasionally by other members of the Mexican pantheon, but in the latter case beads are seldom set in it. The facial paints of the solar god are red or yellow, and these and the golden hair obviously derive from the natural colors of the sun. Jade or turquoise beads were normally set in the sun disk, and clearly have a close association with the sun.

The connection between warriors and the sun was extremely close in ancient Mexico. Warriors fought to capture victims to nourish the sun, and, as a reward, after death on the field of battle or on the sacrificial block, they went to the sky. There they accompanied the sun on his daily journey from the point of sunrise to the zenith (women who had died in childbirth were classified as warriors, and escorted the sun from the zenith to, the western horizon). The finest warriors, as servants of the sun, formed various military orders, of which those of Eagles and Jaguars were most renowned. Eagle and Jaguar were names borne by the sun, and the members of those orders dressed in the skins of those animals. The Toltec painted the bodies of victorious warriors yellow and their faces red, and an Aztec who had taken a prisoner single-handed was permitted the honor of painting himself in the same colors. These, however, were precisely the colors of the sun, as just noted.

We can, accordingly, be sure that the warriors on the frescoes of the Temple of the Warriors with yellow hair set with beads and yellow or red body painting have donned a ritualistic attire in honor of their patron the sun.

Having established that the peculiar hair arrangement worn by warriors on the frescoes of the Temple of the Warriors is one of the attributes of the Mexican sun god, *Tonatiuh*, we must explain why this same unusual coiffure should be combined with unmistakable attributes of *Tlaloc* on the sculptured friezes of the same building.

A rather rare manifestation of the Mexican sun god is *Tlalchitonatiuh*, 'Sun near the earth,' who is the deputy ruler of the 16th week of the *Tonalpoualli* (260-day count) in certain Aztec codices. *Tlalchitonatiuh*, as his name implies, represents the sun at the horizon, and his picture combines the attributes of *Tonatiuh* and *Tlaloc*. This blending may refer to the fact that the sun so frequently rises or sets amid clouds or it might conceivably symbolize also the drinking of the dew by the newly risen sun. In any case, it is clear that the individuals on the friezes represent *Tlalchitonatiuh* because they combine the attributes of *Tlaloc* and *Tonatiuh*. As his impersonators they receive the heart which warriors of the orders of Eagles, Jaguars, and Coyotes(?), in the guises of those animals, offer.

Tlalchitonatiuh must here represent the rising sun, for the *Ciutateteo*, the women who had died in childbirth, would be in charge of any offerings made at sunset. Sahagun records the belief that the warriors who had died in battle or as sacrificial victims gathered each day on a plain, and at the moment the sun rose shouted and beat on their shields.

Although the object, which each impersonator holds, has been identified as a highly ornate spear, it is more probable that it represents the staff which the

sun god was believed to carry, for the dart propelled by means of a spear thrower, not a long-shafted spear, is the weapon of *Tonatiuh*. Duran describes the sun god's staff as very handsome, with its loops and knots of leather and feathers stuck in it. This description and his illustration check fairly well with the befeathered object carried by each impersonator of *Tlalchitonatiuh* on the friezes of the pyramid of the Temple of the Warriors.

On a large boulder at El Baul, Escuintla, on the southern coastal belt of Guatemala, there is an extremely interesting representation of human sacrifice (Waterman 1924). Two men clad in jaguar hides and one in the skin of an eagle are in the posture assumed by sacrificial victims. A priest holds the dripping heart of a fourth victim who is in the same sacrificial position. This last person wears the mask of *Tlaloc* and a headdress which is a simplified form of that worn by the *Tlalchitonatiuh* impersonators at Chichen Itza. All four victims seem to wear long artificial hair, and in one case beads are distinguishable. A head unattached to a body has the same sweeping artificial hair. The date 6 *Quiauitl* is associated with the scene. Here the actors are the same, but instead of offering and accepting the hearts of others, they themselves are the victims. Nevertheless, the same association of Eagle and Jaguar warriors with *Tlalchitonatiuh* holds.

In both cases there is ample evidence that the scenes were sculptured during periods of strong Mexican influence.

Noteworthy in this connection is a carved or molded bowl, found by Linné at Calpulalpan, Tlaxcala. This apparently shows the same deity in association with a Jaguar and an eagle. Here the hair is arranged like the rays of the sun, spreading in all directions, and the general attitude rather suggests that of the diving god.

Maya Epigraphy: Directional Glyphs in Counting

J. Eric S. Thompson

The manner in which the Maya may have indicated whether a Secondary Series was to be reckoned backward or forward has puzzled Maya epigraphists for nearly half a century; and our inability to find the answer to this problem has hampered research, since in the many cases of suppressed starting or ending points of counts it has not been possible to make a reliable reconstruction and thereby fix with certainty the dates with which unknown symbols were associated.

J. Thompson Goodman identified in a general manner a number of directional symbols in his epochal study of Maya glyphs. One of these forms has been generally accepted as indicating a Secondary Series count, but the others have been ignored by all subsequent writers on Maya epigraphy. Goodman, as was so often the case, came closer to the truth than those who followed him but failed to realize the complete meanings involved in these symbols. Actually there are affixes to mark whether the associated Secondary Series should be counted forward to or from the juxtaposed Calendar Round dates. They correspond roughly to our plus and minus signs.

Direction Glyph A (Fig. 20.1a, b) consists of three elements. The first is a prefix, which may be to the left or above the main body of the glyph. This is a well-known character, which occurs in other combinations with a meaning such as "leading to," "falling on," or, perhaps, "ending." The second and main element is also found in many other compounds. For instance, it serves as a variant of the day sign *Muluc*. The third element is a postfix, placed to the right or

below the main element, and which is the so-called torch or vulture symbol. The glyphs on page 126c, d, are merely head variants of Directional Glyph A. The prefix and postfix are unchanged although the latter may become an infix. The head is that also used as the variable element of the Initial Series Introducing Glyph when the month is *Zotz*. Beyer considered it to be that of a mythical serpent; I think it may represent that of a fish, in view of the details which appear to represent fins. Furthermore, in at least one Directional Glyph A (Stela 32, Naranjo), the "comb" sign, which is a known symbol for fish, replaces the central element.

Directional Glyph A frequently stands between a Secondary Series and a Calendar Round date, and indicates that the count is forward to that date; that is, the Secondary Series is to be added to some other date to reach it. Occasionally it occurs with a date which is forward from the preceding one, but where the Secondary Series is suppressed.

Directional Glyph B (Fig. 20.1e, f) resembles Directional Glyph A except that the prefix is absent and a second postfix is added. This additional postfix takes the form of two crescents flanking a variable element which usually is composed of two or three small circles in a line. Sometimes, for lack of space, one of the crescents may be eliminated. There are also head variants of this glyph (Fig. 20.1g, h).

The change in affixes radically alters the meaning of the glyph. Directional Glyph B indicates the departure point of a count forward or, quite probably, the result of a subtraction. Unfortunately, we

20.1. (a–d) Directional Glyph A; (e–h) Directional Glyph B; (i) inscription containing both directional glyphs. (a) Yaxchilan, Lintel 25; (b) Quirigua, Stela F (west side); (c) Chinikiha, step; (d) Palenque, Temple of the Cross (P17); (e) Copan, Altar W'; (f) Copan, Altar I'; (g) Copan, Stela C; (h) Palenque, Temple of the Cross (E12); (i) Copan, Dates 22 and 23, Hieroglyphic Stairway.

cannot be certain as to the order in which glyphs are to be read. If they are to be read in the order in which they occur, Directional Glyph B, whenever it occurs with the second of the two dates joined by a Secondary Series, must convey the idea of a backward count or subtraction. At any rate whenever found with a Secondary Series it is always associated with the earlier of the two conjoined dates.

Many Secondary Series have neither of these two directional glyphs, and few give both. A text which illustrates well the use of Directional Glyph A is that

of the Panel of the 96 glyphs at Palenque. This contains five Secondary Series: four counted forward, one counted back. Immediately before the Calendar Round dates of all forward terminal points head variant forms of Directional Glyph A are carved. There is no Directional Glyph B before the date reached by the one Secondary Series that is subtracted. Instead, there is an eel-like superfix over the day sign. This superfix occurs quite frequently at Palenque, and invariably marks the point of departure of a forward reckoning, or, as in this case, the point reached after a

subtraction (the torch suffix correspondingly seems to mark the terminal of a forward count).

An example of the use of both directional glyphs is supplied by Dates 22 and 23 of the Hieroglyphic Stairway, Copan (Fig. 20.1i). The whole reads something like "A Secondary Series count: 11 tuns 14 uinals and 6 kins counted forward from 'Directional Glyph B' 11 Ahau lead forward to (end on or reach) Direction Glyph A 6 Cimi 4 Tzec." Altar W1, Copan, supplies another clear example which reads "9 uinals and 4 kins counted forward from 6 Ahau 13 Kayab lead forward to 8 Kan." The change in affixes in fact denotes a change in direction "from" becomes "to." Such interpretations may lead to a revision of current renderings of many elements now classed together as ending signs.

Frequently Directional Glyphs A and B are associated with glyphs of unknown meaning, and now that the direction of the count is known, the task of interpreting these unknown symbols should be easier. For example, on Stela J, Quirigua, there are two Secondary Series which have to be added not to the preceding dates but to the Initial Series. Directional Glyph B is in both cases associated with similar glyphs of unknown meaning. These glyphs, therefore, in all probability record that the count is from the Initial Series, not from the last Calendar Round date.

There are, too, other directional glyphs, as, for example, that used in reaching the "Oc" (Goodman's Burner Period) glyph. The whole problem is the subject of a lengthier study now in preparation.

Notes on Sculpture and Architecture at Tonalá, Chiapas

Linton Satterthwaite Jr.

The railroad town of Tonalá, about 150 km east of Tehuantepec and about the same distance west of Izapa, lies at the base of a high escarpment, which flanks the narrow coastal plain. C. Seler-Sachs (1900) and E. J. Palacios (1928) have described two ruins in the neighborhood: one, known as El Paredón, on the ocean side of the plain; the other, La Iglesia, on top of the escarpment and 3 leagues west of Tonalá. My wife and I saw only the latter site in the course of a one-day visit at Tonalá in 1937. Since then Edwin N. Ferndón Jr. and John Corbett have spent about a month at La Iglesia. I understand that they made a survey of the site but did not excavate.

Don Casiano Salazar, proprietor of the ranch on which La Iglesia is situated, supplied us with horses and was kind enough to serve as our guide. He himself is an enthusiastic and most helpful amateur archaeologist. He speaks of La Iglesia as Tonalá Vieja and states that between there and the town is yet another site where there is a carved stela. This, I think, is at the top of the escarpment or else near its base. Clearly, several distinct sites are to be considered as the possible sources of the antiquities now in the town.

The Ferndón map will locate the monuments and mounds which are disposed in more than one group. One of these was mapped by Palacios.

SCULPTURE

Mrs. Seler-Sachs provides drawings of two sides of a stela in the plaza at the town of Tonalá. My bad photograph of one face confirms her drawing as accu-

rate; my photo of the other side was a blank. Her drawing of that side shows a perfectly human figure wearing a grotesque mask in such fashion that his complete face appears between its jaws.

A drawing of the stela at the Tonalá railroad station was published by Palacios. I offer an unfinished drawing of my own, made while waiting for a late train (Fig. 21.1e), because the grotesque head in the bottom panel shows details which Palacios did not notice, and which I did not notice until I examined the drawing later. It appears to be a mask, with a fleshless lower jaw. This seems to be attached to a natural human head, only the lips and chin of which can be seen in profile between the open jaws of the mask. A similar arrangement (in a feline head) can be seen in the headdress of Stela 13 at Piedras Negras, now in the University Museum in Philadelphia, and in a grotesque head in the Chacmool Temple at Chichén Itza. The mask-jaw shows the non-Maya protuberances which Thompson might have predicted, but which Palacios did not draw. This panel was drawn to scale with special care. I was sure only of the two dots shown in the bar-and-dot numeral, whereas Palacios shows four dots. I have no doubt that the number was 9 (with four dots); it is even possible that the two of which I was doubtful were chipped off after he made his drawing. The glyph, presumably a day sign, is hopelessly eroded, the presence of a bar-and-dot numeral certain.

My drawing corresponds with Palacios' in indicating great erosion on the figures right side, but this is because the drawing is unfinished. A poor photo-

graph and my notes show masks at either side of the hips and on each knee, with more certainty than suggested by either drawing; and the photograph, revealing more than either drawing, discloses that the object on the figure's left knee, at least, is a more or less human head and surely not the cushion-like pad to be seen on southern Maya ballplayers, usually on one knee only. No doubt the next observer will be able to recover many details of hip and knee objects, but night-lighting will probably be necessary for good photographs. The left hand seemed to be eroded and I think neither drawing should be taken as evidence that fingers were not originally depicted. The back of the stone is scaled but probably was plain; the (observers) left side is entirely chipped off, but part of the right side remains and is plain.

Surviving height, from base of design, is 1.4 m, width at foot level 0.8 m, thickness about 0.2 m. The plaza stela is 0.75–0.77 m wide, 0.17–0.20 m thick, and stands 1.6 m high. To this must be added something for the feet, now buried, and the plain butt. With these as a guide the original height of the station stone can be fairly estimated at about 1.8 m for the figure plus 0.3 m for the panel at the base, or about 2.14 m for the design. Mrs. Seler-Sachs shows a very short plain butt for the plaza stone, probably the case here, for most of the bottom panel had to be dug out. These dimensions and the fact that the plaza stone, despite its short butt, is carved on both sides, should be considered in forming an opinion as to whether the station stone may have been a ball-court panel, rather than an upright stela.

Figure 21.1a shows Sr. Salazar at La Iglesia beside a stela which he discovered apparently some years after Palacios' visit. Pending a complete numeration I shall use his name for it, "El Soldado." It was chalked to bring out the relief. The reverse, which for convenience I will call the back; is not chalked (Fig. 21.1b), but the only well-preserved edge is chalked (Fig. 21.1c). This is the left side as we face the front. A drawing of this side was made from the original (Fig. 21.1i). I am under the impression that the lower glyph, if more carefully examined, might turn out to be a profile Tlaloc head of the Zapotec type described by Caso; but the drawing is not very reliable. I am fairly sure that the elongated elements at the left belong to the design on the back, this being carried around a rounded edge. To the right of these (whether I misconstrue my faulty notes or not) is the panel with glyph-like elements, certainly not Maya, with the glyph just noted at its base. It shows, I think, a certain vague resemblance to the back of a statue found by R. Burkitt at El Vicente, near Palo Gordo, Suchitepequez, Guatemala (Fig. 21.1j). The other edge of the Tonalá stela is badly scaled, but a good photo-

graph shows a small well-preserved section indicating a similar "inscription" containing rectangles.

There is a piece of sculpture which we can provisionally call "stela fragment," at Sr. Salazar's home in Tonalá (Fig. 21.1f). According to him this lay about 3 m from the "soldado" stela, on ground a little higher. He found the stela nearly buried, its best-preserved edge up, and re-erected it. If we consider the staff or spear-carrying man of figure 1a as the "soldier," then the question is raised whether the fragment is not the top of this stela, and the side drawn in figure is the head of the "soldier."

According to my notes pieces are of "the same mottled stone," which, to my inexperienced eye, is the same as that of the plaza stela but somewhat different from that of the station stela. This material occurs as bedrock at La Iglesia.

As there is a good probability that fragment and stela belong together, I would suggest that the next visitor make a paste-and-paper cast of the broken top of the stela and see if it fits the fragment now in the town. The stela is 1.5 total design height with 47 cm of this plain butt, 53 cm (front) and 44 cm (back) wide, 31 cm thick. The width of the fragment is 61 cm, thickness 20 cm. These measurements do not suggest a fit, but I do not know whether my dimensions for the top of the stela are correct. If two stelae are involved, the main part of the fragment presumably awaits discovery and should be in the vicinity of "El Soldado."

The (observers) right side of the stela is rounded; the other is comparatively flat, and not at a right angle to the front. The edges of the fragment are rounded on both sides and somewhat carinate. The ridges become sharper toward the top, which has the form of a gigantic celt. The side not illustrated carries a similar but not identical head and headdress, the latter with a similar staring eye and mouth-curl.

A slab, perhaps roughly shaped and engraved in the form of a frog or toad (about 0.6 by 0.53 by 0.15 m.) lay some meters to the left of El Soldado (Fig. 21.1d, g). Soldado and frog are near the edge of the cliff, well removed from the mound group described by Palacios. Figure 21.1h, is a very hurried and poor sketch of a stone in the neighborhood of that group, behind and above the "paved way" illustrated by Mrs. Seler-Sachs. It was found by Sr. Victor Escobar, an associate of Sr. Salazar. It is centered in front of, and about 5 m from, a mound about 1 m high. The drawing should not be relied on too heavily, but the Tlaloc-like fangs seem perfectly clear. The stone is carinate, with the ridge running down the front.

On another hilltop, near a large platform, is a boulder known as "El Sillon," about 3 m long, with part of its top cut out to form a flat surface at one side and end.

21.1. Sculpture at Tonalá, Chiapas: (a) front of "El Soldado" stela, La Iglesia, Tonalá; (b) back of a; (c) side of a; (d) slab in form of toad, La Iglesia, Tonalá; (e) design on stela, Tonalá station; (f) design on stela fragment, Tonalá; (g) design on d; (h) sketch of stone at La Iglesia; (i) panel with glyph-like designs on left side of a; (j) design on back of statue, San Vicente, near Palo Gordo, Suchitepequez, Guatemala.

Near the ranch house was a stone (1.6 by 0.5 by 0.2 m), said to have been brought from the neighborhood of the Soldado stela. It was somewhat irregular in shape and one edge had been nicely tooled to a flat surface. Neither this nor the "sillon" appear to be architectural elements, though perhaps they should not be described as sculpture either.

ARCHITECTURE

Palacios' plan and description give a good idea of the type and disposition of the mounds here. There is more than one such group, and we can look for their relationships when Ferndon's map becomes available. I can add a few notes to supplement those of Palacios on the architecture.

The terracing of at least two platforms carried what in the southern Maya area would be called an apron molding, doubtless the same as the "cornice" described by Palacios. In one case this was formed of three courses of stone, the faces beveled to give the slope. Where noted, this element is not used in the Maya manner.

The opening of a subfloor drain, 0.45 m high and 0.55 m wide, gives onto the top of another and lower terrace, and a shallow open channel leads from it across the top of the latter.

The vestiges of building walls will, with only minor clearing, yield more or less complete ground plans. Even without any clearing it was possible to note that the temple at the top of Mrs. Seler-Sachs "paved way," its side toward the latter, probably had only a single doorway about 2 m wide, and a single room of about that depth, with walls 0.8 or 0.9 m thick. In another case a rear building wall was 0.68 m thick. Two piers were placed 2.4 m forward of this, forming a room 2.4 by about 11 m, with three doorways about 2.8 m wide. The one completely visible pier was 0.7 by 1.8 m. The front of the piers is 0.8 m behind a plinth or step-down; there were here some hints that the side walls extended forward to enclose a second and front room at a lower level; but this was uncertain, and such a room might, if existent, be secondary.

Another building probably contained only one room about 2.6 m (or more) by about 11 m, with a single front doorway 2.4 m wide. Behind the doorway and against the rear wall was a small mound of debris, presumably the ruin of a bench altar or a "sanctuary," such as those figured at Quiengola. If the latter, it was miniature in size, such as that in Pyramid A-I at Uaxactun.

Palacios was quite correct in describing some of the masonry, as "megalthic," and I agree with him that all the stone had been split off from laminated

beds. But there is wide variety in the size of the slabs selected for different structures, and in one case a megalthic platform seemed to have been secondarily extended with a wall of small slabs. In one case I noted a building platform, about 1 m high and composed of much smaller stone than its basal platform, and the wall of the building composed of small thin slabs only. Like Palacios, I noted absence of mortar, but pending excavation I think this question should be left open. If poor in quality, it may have washed out of the exposed faces. Some chinking was evident, as well as a corner of nicely fitting, cut stone without chinking. Although stone-dressing was probably kept to a minimum, my impression was that the local builders knew perfectly well how to do it.

No free-standing walls are now higher than about 0.5 m. This, coupled with the scarcity of debris, guarantees that roofs were not vaulted and, I think, that walls were of perishable material above a height which may have varied but which was hardly more than a meter anywhere.

In view of "artificial stones" laid in clay, reported at Quiengola, we need not necessarily conclude that the walls were partly wood or wattle-and-daub. Ordinary adobes or the Quiengola variety (in which lime, gravel, and crushed stone seem to have been mixed) could presumably have weathered away and been washed out, leaving only the lower stone portions. Lime plaster was not noted. Unless this was available for weatherproofing flat roofs, probably thatch roofs should be postulated. In this connection I can testify that in carefully digging many nonvaulted buildings in the Maya country, I found sure remains of lime plaster on walls and floors but only after large areas had been thoroughly searched for it. I think that beam-and-mortar roofs should at present be considered as possible here.

At the mound behind the head of Figure 21.1h, "some small cut veneer" stone was observed, with the additional note that, "Stone used here on edge frequently, usually large and well-cut (in retaining walls)." It would be well to distinguish between veneering of free-standing vertical walls and that of sloping substructure walls when using veneer as a trait of chronological or distributional value. My notes do not make it clear whether veneering of free-standing building walls was seen at Tonalá.

Such hasty notes as these should not be used as a sure basis for theory; I offer them merely for use in forming or questioning tentative hypotheses, and especially so that the next visitor, with more time, will be led to confirm or correct them. The importance of Tonalá in the question of tracing southern Mexican influences on the Pacific coast of Guatemala has been noted elsewhere.

Maya Epigraphy: A Cycle of 819 Days

J. Eric S. Thompson

In five Maya inscriptions the month position of an Initial Series is separated from the context by an intervening Secondary Series and date, together with six (in one incomplete text four) explanatory hieroglyphs. In four cases the Secondary Series is subtracted from the Initial Series to reach a day with a coefficient of one; in the fifth example a subtraction was almost certainly made to reach a day with a coefficient of one, although the Secondary Series

and the day are destroyed. Only the month position remains.

In one text (Stela K, Quirigua) the parenthetical clause interrupts the Lunar Series; in the remaining examples it follows Glyph A of that series. There are no other known cases of an interruption of an Initial Series.

These Initial Series with their parenthetical clauses are:

Palenque Stela 1	A	A1-B5	9.12.6.5.8	3 Lamat	Initial Series
		A9-B9	1.10.1		Subtract
	A'	A10	9.12.4.13.7	1 Manik 10 Pop	
		A11-B11		Explanatory glyphs	
Yaxchilan Lintel 29 and 30	B	A1-A4	9.13.17.12.10	8 Oc	Initial Series
		E1-F1	1.1.17		Subtract
	B'	E2-F2	9.13.16.10.13	1 Ben 1 Chen	
		E3-F5		Explanatory glyphs	
		G1		13 Yax	Month of Initial Series
Yaxchilan Stela 11 (right/left sides)	C	B'1-B'7	9.16.1.0.0	11 Ahau	Initial Series
		C'2-C'3	1.3.6		Subtract
	C'	C'4-C'5	9.15.19.14.14	1 Ix 7 Uo	
		C'6-C'9		Explanatory glyphs	

continued on next page

		C'10		8 Tzec	Month of Initial Series
Yaxchilan Stela 1	D	A1–D3	9.16.10.0.0	1 Ahau ¹	Initial Series
			1.1.10		Subtract
	D'	E2	9.16.8.16.10	1 Oc 18 Pop ²	
		E3–F6		Explanatory glyphs	
		E7		3 Zip	Month of Initial Series
Quirigua Stela K	E	A1–A5a	9.18.15.0.0	3 Ahau	Initial Series
		A6	10.10		Subtract
	E'	B6b–A7a	9.18.14.7.10	1 Oc 10 Kayab	
		A7b–C2a		Exploratory glyphs	
		C4		3 Ahau 3 Yax	Day and month of Initial Series
		D4–		Further explanatory glyphs	

¹ Presumably on eroded section.² Day sign obliterated.

Only in the case of D' is the reading clouded. However, 18 Pop is perfectly clear, and in view of the parallel cases, the restoration suggested is almost certainly correct. For reasons of brevity it will be assumed that this reading is not open to question.

The explanatory glyphs obviously treat of the same subject, although there are certain differences, due possibly to the use of variable forms of the same glyph or substitution of another glyph with the same meaning (Fig. 22.1a–e). All five texts include a glyph with a coefficient of one, which, except in Text A', occupies the last place, immediately preceding the detached month sign of the Initial Series. This is the head of a rodent with the so-called bone glyph as affix, which forms one of the elements of Glyph B of the Lunar Series. To judge by full-figure representations of this animal at Acanceh, where it is shown with a long bushy tail, it is meant to indicate a squirrel.

The principal features of the various glyphs, numbered in the sequence in which they occur, are as follows:

1. Obviously the same glyph in all cases. In all texts except A' it, like the month sign Pax, has at the top an opening, through which in three cases pass two diverging curls. There is an infix resembling the Chuen sign, and in three cases a lunar infix or postfix. This is Gates' Glyph 92, which occurs very frequently in the codices.
2. In Text B' this is a kin sign with a half kin as superfix. In Texts C' and D' this is replaced by the head of a god with a Roman nose and with an ending sign in front. In view of the kin sign in

Text B' these may be portraits of the sun god but they may represent Glyph G6. In Text E' the second glyph is a Cauac sign with an ending sign, but the partly obliterated third glyph appears to be the same face with a Roman nose.

3. In Texts C' and D' the central element consists of crossed bands. There is a "flame" affix and, in the case of Text C, what may be a coefficient of nine, but the details are hard to make out, and it is possible that this element is not numerical. One is reminded of the crossed bands in planetary bands. In Text B' a grotesque head with affix replaces this sign. In Text E' this glyph appears to be suppressed.
4. In Texts B'–D' this is the "beetle" glyph, also called Glyph Y, which occurs in some Lunar Series, particularly at Yaxchilan. The corresponding glyph in Text E' is largely obliterated.
5. In Texts B', C', and E' this is a grotesque head with a branching flame-like element emerging from the forehead. In Text A' this same head occurs but not in the correct sequence. In Text D' a grotesque head can be made out, but it is not possible to say whether the flame-like element is present.
6. This is the "squirrel" glyph to which attention has already been called.

To this group of Initial Series with their parenthetical clauses may, perhaps, be added a sixth. This, however, differs from the rest in that it does not interrupt the Initial Series but immediately follows the Lunar Series thereof:

22.1. Glyphs in parenthetical clauses: (a) Palenque, Stela 1; (b) Yaxchilan, Lintel 30; (c) Yaxchilan, Stela 11; (d) Yaxchilan, Stela 1; (e) Quirigua, Stela K; (f) Yaxchilan, Lintel 29, supplementary glyphs; (g) Yaxchilan, Stela 1, supplementary glyphs.

Palenque	F	A1–A9	12.19.13.4.0	8 Ahau 18 Tzec	Initial Series
Temple of the Cross		B13	1.0		Subtract, lunar variant for 20
		A16–B16	12.19.13.3.0	1 Ahau 18 Zotz	
		A14–B15		Explanatory glyphs	

In this text the explanatory glyphs differ from those already discussed. The first is the glyph with Pax and Chuen elements but without a lunar postfix. The second glyph has the branching “flame” element

emerging from a glyph which from other examples can be shown to represent the top of the head of the god who normally has this element. The other two glyphs do not figure in the texts already reviewed.

In several of the texts there are supplementary glyphs before or after the parenthetical clauses, to which they appear to be related (Fig. 22.1f, g). Also, on Stela K, Quirigua, the "Pax-Chuen" glyph is repeated, complete with lunar postfix following the detached conclusion of the Initial and Lunar Series.

As in all six texts the day sign coefficient reached by subtraction is one, the intervals between these positions must be multiples of thirteen. In days these intervals are 11466, 15561, 3276, 16380, and 1433250. However, the highest common factor of these intervals is not thirteen but 819. Such a high common factor could hardly be the result of chance. The odds are over a thousand to one against it. This number is composed of 91×9 , or 117×7 , or 273×3 , or $9 \times 7 \times 13$.

The numbers nine, seven, and thirteen are of great ritualistic importance. Nine represents the nine underworlds and the nine lords of the night, seven probably the seven layers of the earth, and thirteen the thirteen heavens. The number ninety-one is ritualistically and arithmetically important, but its multipliers, are four, five, and twenty in the Dresden Codex, not nine.

Since 819 is divisible by nine, the same form of Glyph G of the Lunar Series, G6, is required by all the parenthetical clauses. In this connection it is interesting to note that Texts B, C, and D, all of which are from Yaxchilan, are followed by a glyph with a coefficient of six. The glyph itself is a simplified face above what is probably a lunar affix. In one case half the face is covered with crosshatching, a symbol for black and presumably, by extension, darkness. (cf. crosshatching of kin sign when employed as lord of night.) One wonders whether this face with coefficient of six can refer to the fact that the sixth lord of the night and underworld rules over the parenthetical dates. It is also worth noting that it was this same sixth lord of the night and underworld who ruled over the opening night of the thirteen-day week in which 13.0.0.0.0 4 Ahau 8 Cumhu fell. His reign started at 12.19.19.17.17 1 Caban 5 Cumhu, three days before 4 Ahau 8 Cumhu. In fact this 1 Caban 5 Cumhu is the starting point of the 819-day cycle.

As only once in every sixty-three times will a day with a coefficient of one also mark the start of the 819-day cycle, the fact that this first day with a coefficient of one before 4 Ahau 8 Cumhu is a base in the 819-day cycle argues strongly for that count being primarily ritualistic.

The fact that the base of the 819-day cycle falls three days before 4 Ahau 8 Cumhu implies that the gods who were in power at the start of the period continued to exercise certain influence throughout its

span, thereby giving further scope to the balancing of good and bad influences inherent in the Middle American calendrical divination. Such a concept certainly existed. On the Mexican tableland the god of the thirteen-day "week" shared power with the patron of each day until a fresh god of the "week" entered into power with the return of a day with a coefficient of one. Similarly among the Ixil Maya the year-bearer deity who rules over a year bearer with a coefficient of one, continues to influence human affairs until, thirteen years later, another year bearer with coefficient of one enters (Lincoln 1942:115).

It is obvious that this cycle of 819 days must involve more than a grouping of lords of the night and underworlds. The number is too high, for after 117 days the cycle would have been completed, each lord of the night would have ruled over a thirteen-day period. However, only after 819 days would sequences of nine lords of the underworlds, thirteen lords of the heavens, and the presumed seven lords of the earth once more coincide.

The existence of a series of thirteen gods presiding over consecutive days is implied by the Maya face numerals. There also occurs in the Aztec codices Borbonicus and Aubin Tonalamatl a repeating series of thirteen deities. Seler considered these to be the rulers of the thirteen hours of the day, but as one is attached to each day sign, it is much more probable that they ruled the consecutive days of each thirteen-day week, and therefore corresponded to a certain degree to the head-variant numerals of the Maya. In the account of the creation in the Chilam Balam of Chumayel the thirteen gods fight the nine gods. The implication is that it was a struggle between the heavens and the underworlds.

There is no strong evidence for the existence of a group of seven terrestrial deities, but in this same account of the creation there is mention of a certain Ah Uuc Chekmal, 'he who fertilizes the maize seven times,' who came from the seventh stratum of the earth (or the seven strata of the earth). Since both the group of thirteen gods and the group of nine gods bear collective names used in the singular, it is not impossible that Ah Uuc Chekmal is really the name of a group of seven gods who are associated with the seven layers of the earth. Mr. Ralph L. Roys informs me that he sees no valid reason why the Maya text should not be taken to refer to seven deities and seven strata, not necessarily to a single deity from the seventh stratum.

It is, probable, therefore, that the 819-day cycle developed from a desire to mark the coincidence of the starting points of these three series of deities. It is also possible, however, that the 819-day cycle had, in addition, an astrological significance.

The cycle is 117×7 . In 117 the Maya had a good approximation to the synodical revolution of Mercury (115.877 days). Such an approximation would have suited them admirably because it complied with one of their most important desiderata, for it constituted a re-entering cycle in terms of the 260-day almanac. At the end of 117 days the day coefficient would be the same. However, in order to achieve a return to the same coefficient and day, the 117-day cycle would have as its next highest order 117×20 . In this case the multiplier of 117 is seven. Therefore, it is clear that any connection with Mercury would be a secondary, not a primary, purpose of this 819-day cycle.

The position of the parenthetical clauses immediately after or, in one case, in the middle of, the Lunar Series, and the lunar elements which enter in then suggested the possibility that a lunar meaning might also be involved in this count.

Faced by these astronomical problems, I turned to Dr. Maud W. Makemson, Director of Vassar Observatory, and to Dr. Alexander Pogo, both of whom most kindly undertook the many laborious calculations needed to determine the positions of Mercury and the moon on the various dates in question. Because both specialists possess that rare combination, a mastery of both practical and Maya astronomy, their many suggestions were most useful.

An examination of the positions of Mercury on the ten dates in question, using the Ahau equation 584285, produced no pattern. On Dates A, C, and D Mercury was 23° , 21.5° , and 19° east of the sun, which were possible, but unverified, points of greatest eastern elongation. On Date B Mercury was 14° west of the sun; on Date E, 15° east of the sun. The stars near which Mercury moved on those five dates similarly failed to show any pattern. Periodicity would, of course, be absent whatever correlation was used. It was therefore clear that the five Initial Series dates did not record observations of some significant point in the revolution of Mercury in contrast to calculated positions in an uncorrected cycle recorded in the parenthetical clauses.

On Date A' Mercury was three or four days before inferior conjunction; on Dates B' and C', 27° east and 27° west, respectively, of the sun, points of greatest elongation; on Dates D' and E', 14° west and 17° east, respectively, of the sun. Again there is a complete lack of pattern, disposing of the possibility that on these dates Mercury was at important points both actually and cyclically.

Because of the shortness of the revolution of Mercury and our uncertainty as to what phenomena would interest the Maya astronomer, only a clear and

orderly series of phenomena can have any meaning. On not more than two of the ten dates in question was Mercury near the same constellation, thereby disposing of the possibility that conjunction with stars or passage through celestial compartments was involved. It is, therefore, clear that the 819-day cycle did not primarily involve Mercury.

In connection with a possible lunar meaning being attached to this cycle, Dr. Pogo pointed out that 819 days were within a day of thirty sidereal months and at the same time they approximate $27\frac{3}{4}$ synodical months. After 819 days, therefore, the moon would be in about the same position in relation to the stars but its age would have decreased by one phase. However, Dr. Pogo notes that as thirty sidereal revolutions of the moon are actually 819.65 days and twenty-eight synodical revolutions are 826.86 days, an error will rapidly accumulate. Thus the 819-day cycle could not have been used without correction to calculate the actual positions of the moon against her stellar background, except for relatively short periods.

Again Drs. Makemson and Pogo kindly volunteered to calculate the positions of the moon on Dates A-E and A'-E' in view of the possibility that the Initial Series in question might record observed positions of the moon with regard to the stars, whereas the parenthetical clauses might record calculated positions in an uncorrected cycle, or, alternatively, the parenthetical clauses might record occasions when the moon was in conjunction with certain important stars, both by observation and according to the uncorrected cyclic reckoning. Again no pattern emerged.

Dr. Makemson has suggested other ways in which the 819-day cycle might have been used. A discussion of these would take us too far afield, and, in any case, would come best from her pen.

There remains another line of approach, that of linking the endings of the 819-day periods to the katuns current when the monuments in question were dedicated.

The dedicatory date of the lintels with which Date B' is associated is 9.17.0.0.0. The distance from Date B' to 9.17.0.0.0 is 22827 days. This is within a day of 197 revolutions of Mercury (22827.8 days). It is also 773 moons (22827.15 days), and exactly sixty-two and a half solar years. Also 1 Chen is a determinant of 18 Cumhu: $1 \text{ Chen} + 197 = 18 \text{ Cumhu}$ (Gregorian correction is $197\frac{1}{2}$ days). The Maya priest may have reasoned more or less as follows:

The 819-day cycle ended 377 days (just one synodical revolution of Saturn) before the Initial Series. As a rule we don't record these cycle endings, but in this case it can be brought

into an interesting relation to the dedicatory date, 9.17.0.0.0 13 Ahau 18 Cumhu. On both dates there was a new moon, and on both dates Mercury was at the same point in the heavens (maximum eastern elongation). Moreover the sun is just half a revolution away at 1 Ben 1 Chen (Date B') from where it will be at 9.17.0.0.0 13 Ahau 18 Cumhu. In the first case it is thirty-three days after the summer solstice; in the second, thirty-three days after the winter solstice. Finally, 1 Chen occupied at Cycle 13 the same position in the solar year that 18 Cumhu occupied in the year then current.

The lower part of Stela 1, Palenque, on which Date A' is recorded, is missing, but it is probable that the dedicatory date was 9.12.10.0.0 or 9.13.0.0.0. If the latter, a reason for giving the end of the 819-day cycle exists in the fact that 9.13.0.0.0, Date A, and Date A' all have the same moon age, which according to the lunar series was nineteen days. Also the moon number of both 9.13.0.0.0 and Date A' would be five according to the uniform lunar system, since the interval between them (186 moons) is divisible by six. The Initial Series is not in the uniform system, but records the moon number as five. It is an interesting possibility, although nothing more, that when Stela 1 was erected Palenque had adopted the uniform system, but gave the moon age of the Initial Series by the old system, thereby reaching the same moon number and moon age for all three dates. Lastly, 9.13.0.0.0 and the Initial Series (not in this case the parenthetical date) are separated by thirteen and a half solar years (the remainder is 183.8 days), the two dates lying about six days before the vernal and autumnal equinoxes. The Initial Series is also, as Teeple pointed out, a determinant of 9.13.0.0.0, for by Maya reckoning the sun on 6 Zac at Cycle 13 was in the same position as at 8 Uo in current time. $6 \text{ Zac} + 187 = 8 \text{ Uo}$ (Gregorian calls for a correction of 189 days).

Date C' was a new moon according to Maya calculation. Date C is recorded on this monument as five moons twelve days according to the uniform system. The Secondary Series of 1.3.6 equals fourteen moons and twelve days, thereby indicating a moon age for Date C' of three moons no days. The dedicatory date of this monument is uncertain. The Initial Series falls in Katun 9.17.0.0.0 13 Ahau 18 Cumhu, which, as we have already seen, was also the date of a new moon, and furthermore was the third moon. Date C also occurs on Lintels 29 and 30, the dedicatory date of which was certainly 9.17.0.0.0. Accordingly, it is quite probable that this is the dedicatory date of Stela 11 as well, or, failing that, marked the end of the current katun.

There is no solar association linking these two dates, but it may be significant that on both dates the first god of the series of seven (terrestrial?) deities was in power.

Stela 1, Yaxchilan, which carries Date D', was erected at 9.16.10.0.0 (Date D). The current katun was, therefore, again, 9.17.0.0.0 13 Ahau 18 Cumhu. There is, however, no direct relation between Date D' (1 Oc 18 Pop) and the katun-ending. Yet we have seen that solar half years and the same moon age seem to be the matters which interested the Maya in these particular texts. Half a year back from the current 19 Cumhu is 9.16.8.6.3 2 Akbal 16 Chen. However, 16 Chen is itself the determinant of 18 Pop at that date: $16 \text{ Chen} + 207 = 18 \text{ Pop}$ (Gregorian correction calls for 209 days). Also 16 Chen is the same moon age as 18 Pop, since 207 days is within a third of a day of seven moons (206.7 days). In other words 16 Chen is half a year away from 18 Cumhu, and 18 Pop is the anniversary of 16 Chen placed at Cycle 13, and the two linked dates of 18 Pop and 16 Chen have the same moon age. Also God G6 ruled on both dates.

Stela K, Quirigua, which carries Date E', has the dedicatory date 9.18.15.0.0. (Date E) as the Initial Series. The current katun was therefore 9.19.0.0.0 9 Ahau 18 Mol. The interval between Date E' and Katun 19 is 2010 days. This is one day more than five and a half solar years (2008.8 days). The katun ended, according to the correlation here followed, on June 28; Date E' fell on December 26, both dates being a few days after the solstices.

As Date E gives the moon age as eighteen days, the moon must have been thought to have been full (fifteen days old) at Date E'. The moon at 9.19.0.0.0 would have been seventeen days old by calculation from either of those points.

The precise secondary meaning of the early date (Date F') on the Temple of the Cross inscription is not clear. It is, however, of interest to note that, as pointed out by Teeple several years ago, the Initial Series is a determinant of 9.10.10.0.0 13 Ahau 18 Kankin. This last date, however, can not be connected with Date F', but the correction according to the Gregorian calendar would be 182 days. The Maya, however, reckoned this as 180 days. Furthermore, as Bowditch pointed out many years ago, the early date 1.18.5.3.2 9 Ik 15 Ceh falls at a time when a correction of half a solar year was required. It is, accordingly, possible that this date, indirectly grouped with the series already discussed, is in some way at present not clear, associated with solar time.

The various associations just discussed are presented below:

<i>Text</i>	<i>Parenthetical Dates</i>	<i>Katun-Ending</i>	<i>Interval In Days</i>	<i>Lunar Associations</i>	<i>Solar Associations</i>
A'	9.12.4.13.7	9.13.0.0.0	5493	Same moon age	Half-year advance over Initial Series. ¹
B'	9.13.16.10.13	9.17.0.0.0	22827	Same moon age	Half-year advance. ²
C'	9.15.19.14.14	9.17.0.0.0	7266	Same moon age (new moon)	None. ³
D'	9.16.8.16.10	9.17.0.0.0	207	Same moon age	Half-year advance. ⁴
E'	9.18.14.7.10	9.19.0.0.0	2010	Two days difference in moon age	Half-year and one day advance. ⁵

¹ Date A also same moon age. Solar positions close to equinoxes.

² Mercury at same position on both dates. Same god in series of seven.

³ Same god in series of seven ruled on both dates.

⁴ Association is with 9.16.8.6.3 2 Akbal 17 Chen, the current determinant of 9.17.0.0.0, but this is not actually given in the text. Same lord of night (G6) ruled both dates 16 Chen + 182 = 18 Cumhu.

⁵ Solar positions close to solstices. Moon at E' was full.

If the above interpretations are correct, the Maya did not bother to record every starting point of the 819-day cycle but only those on which there were lunar or solar relationships, or both, with the current katun-ending, presumably links with the series of nine and thirteen gods. As already noted, lunar elements occur in all the parenthetical clauses except Text A'. Text B' has a kin glyph surmounted by a second-kin glyph cut in half, conceivably to indicate a solar half year. The corresponding glyph in the remaining complete texts is the head of a deity possibly this is the head of the sun god, although the usual attributes are lacking. Alternatively this head might represent God G6, who reigned over the first night of the 819-day cycle.

In summary: The Maya had a ritualistic cycle of 819 days, which marked the return to the same starting point of the series of thirteen, nine, and seven deities, probably corresponding to the celestial, infernal, and terrestrial deities. The starting points of the

819-day cycle were seldom recorded on monuments of the Initial Series period, for only five indubitable cases have been reported. These are arranged in a unique manner as parenthetical clauses within the Initial Series to which they are joined. Presumably only those which were of enhanced importance because of certain coincidences of an astronomical or a calendrical nature were recorded. Possibly those were chosen which showed a lunar or solar relationship, preferably both, with the current katun-ending. If a determinant relationship existed so much the better. Only Yaxchilan, Palenque, and Quirigua, as far as we know, ever recorded a text of this nature.

Although 819 is a good approximation to thirty sidereal revolutions of the moon, no evidence was uncovered that the Maya used the number in calculations of that nature. Similarly, the approximation of seven synodical revolutions of Mercury to 819 days seems not to have been of primary interest to the Maya.

The Periods of Tribute Collection in Moctezuma's Empire

R. H. Barlow

R.C.E. Long (The Payment of tribute in the Codex Mendoza. No. 10 of this series) has recently pointed out that the tributary provinces of Moctezuma's empire made their payments yearly, half yearly, and "quarterly," that is, what is termed every eighty days on the four festivals of Tlacaxipeualiztli, Etzalqualiztli, Ochpaniztli, and Panquetzaliztli. The present paper is intended as an extension of his remarks.

As evidence for his quarterly tribute dates he cites the Humboldt Codex I, part of a manuscript originating, as Lic. Salvador Toscano (1943) has shown, in southeastern Guerrero. It may be added that these same four festivals of the Humboldt Codex I appear in a tribute codex from the modern state of Morelos, where the "quarterly" payment (to new masters) was maintained well into the sixteenth century, as we read in the *Suma de Visitas* no. 163. This supplementary codex is the Mauricio de la Arena from Tlaquiltenango, Morelos (a part is published in Paso y Troncoso 1897:273-78). Dating from about the time of the Spanish conquest, the codex conserves the old calendar system despite the Christianized names of some of the tributaries listed. Two of the fiesta-symbols, those of the festivals of Ochpaniztli and Panquetzaliztli, which indicate tribute periods in the Humboldt Codex I take the same form as in that codex. Tlacaxipeualiztli is represented (as in Codex Mendoza, f. 47r) by Xipe's conical cap (*yopitzontli*) instead of by his whole head. The fourth festival, that of Etzalqualiztli, seems at first inspection to be absent. Between the symbols of Tlacaxipeualiztli and Ochpaniztli, however, just where Etzalqualiztli

should occur, is a glyph of a vessel filled with liquid. Now Etzalqualiztli was one of the principal feasts of Tlaloc, and is represented in the Humboldt Codex I by the mask of the rain god. Clearly, the artist of the Mauricio de la Arena has merely chosen another attribute of the same deity, one of the vessels in which rain is stored in his heaven of Tlalocano. Thus the same four tribute dates shown in the Humboldt Codex I for a town in southeastern Guerrero are confirmed by the Mauricio de la Arena from a town of southern Morelos. (We may surmise that the four rosette day-symbols of the Tlatelolco page, Codex Mendoza, f. 19r, refer to these same feasts.)

In the unique case where all payments were twice yearly, two of these same festivals, Tlacaxipeualiztli and Ochpaniztli, are retained. Cooper Clark points out that this is the only place (f. 47r) where month symbols are painted in the Codex Mendoza. This slower rhythm is caused by the distance of the indicated province (Soconusco), which was the most southerly tributary of the empire.

The yearly, half yearly, and "quarterly" payments are not the whole picture. To them we must add the payment, six times a year, which was received by Texcoco from the province of Quauhnahuac. This is somewhat at variance with the version of the *Matricula de Tributos* and the Codex Mendoza, but our source is certainly trustworthy. In Lehmann's *Die Geschichte der königreiche von Colhuacan und Mexico* (1938), verse 131. (the most reliable edition of the document) in addition to the four festivals already discussed, those of "Tecuilhuitl" (Tecuilhuitontli or

23.1. Hieroglyphs for months of payment of tribute: (a–c) Tlacaxipeualizli, Humboldt Codex I, Mauricio de la Arena, Fragment I, Libro de Tributos; (d–e) Etzalqualiztli, Fragment I, Libro de Tributos; (f–h) Ochpaniztli, Fragment I, Libro de Tributos; (i, j) Panquetzaliztli, Fragment V, Libro de Tributos

Uei Tecuilhuitl, the text is defective) and Quecholli figure as tribute dates. Unfortunately, the list is in writing, and there are no glyphs for theme.

We see, then, that certain festivals seem to have served as a framework for tribute in widely scat-

tered parts of Moctezuma's empire, being increased or decreased as distance demanded. It is not difficult to see why nearby Quauhnahuac paid tribute three times as often as Soconusco, on the remote and steamy frontier of the southlands.

Notes on Glyph C of the Lunar Series at Palenque

Heinrich Berlin

Since J. E. Teeple (1931) established, according to four cases where he studied Glyph C, that the Maya of Palenque used exactly 6 moons to a group, nobody, so far as I can see, ever tried to prove or refute this theory; on the contrary it was generally accepted. Nevertheless, during the excavations made in 1940 and 1941 under the Mexican government two inscriptions containing Glyph C were found which do not at all harmonize with Teeple's ideas.

Let us examine the problem as it was set by Teeple. He compared the Initial Series of the Inscriptions of the Temple of the Cross, of the Temple of the Sun, and of the Temple of the Foliated Cross with the Initial Series of Stela 1 and found that the corresponding Glyphs C of each inscription are separated from each other as if they were arranged in lunar half-years of 6 months. Thence he concluded, although with some reserve, that periods of exactly 6 moons were always used at Palenque.

Now, in an inscription in stucco discovered in May 1941 the Initial Series 9.10.14.5.10 3 Oc 3 Pop was accompanied by Glyph 6C. If Teeple's theory is correct, there should be a remnant of precisely 6C when one divides by groups of 6 moons, the difference which lies between any of the lunar bases from which his given points are reckoned and 9.10.14.5.10. The nearest of these points is 9.12.6.5.8, 5C 19 days, the date of Stela 1. The distance between these two dates is

9.12.6.5.8	5 C 19 days
9.10.14.5.10	
1.11.17.18	= 11518 ^d

According to Teeple's lunar formula for Palenque, 81 moons = 6-11-12, 6 moons equal 177.185^d. Now 11518^d:1770185 = 65 groups of 6 moons + 0.975^d. If we subtract from 5C 19 days of Stela 1 the remainder of 0.975^d, we reach 5C 18 but not 6C as the inscription records.

In 1942, when cleaning the basement of the Temple of the Sun, Miguel Angel Fernandez found some fragments of an incomplete inscription (Fig. 24.1). It reads:

9.12.6.5.8	5C 19 days
-9.10.14.5.10	
1.11.17.18	= 11518 ^d

In the drawing, made also by Sr. Fernandez, the numerical bar of the Kayab does not come out very clearly, but it is my recollection that the small piece which remains is the beginning of a bar and not of a dot. The space between the glyph and the border is narrow and is such as would hold a numerical bar, but not numerical dots which in this inscription have a greater diameter. As the date 9.12.19.11.12 5 Eb 5 Kayab is very frequent at Palenque, it is highly probable that the present inscription originally occupied that position in the Long Count. On the other hand, the Glyph G seems to be of the G3 form, not G4 as here required. Comparing this date with Stela 19 we see that, if it were to fit Teeple's theory, it should read 2C 11, instead of 3C 11 as it actually does. Since the value for D of the inscription is in perfect harmony with the computed one, this can be adduced as evidence for the correct placement of the date.

Palenque T of S Sanc Jamb Top

24.1. Inscription on tablet at Palenque (from a drawing by Miguel Angel Fernandez).

In view of the new data presented, one cannot any longer maintain the theory that the Maya of Palenque uniformly grouped their moons in sixes. It is noteworthy, however, that both the last two inscriptions are in complete agreement with Teeple's Period of Uniformity. This fact is not so extraordinary especially, in the case of the last date, 9.12.19.1.12, for that falls with in the Period of Uniformity, provided that it really started at 9.12.15.0.0 as Teeple states. This conclusion involves another one: that the supposed differences between Palenque and Copan are not so

easily demonstrable and that it is still more difficult to prove the cessation of activity at Palenque, the date of which is still unknown.

In connection with the lunar reckonings at Palenque, one might add that the shield of the stairway of Palace House C does not read 11-11-13 as Teeple states, relying only on the drawing by Maudslay. According to my field notes it reads 6-11-13 (see also Maler's photograph, pl. 13, in Seler 1915a). The reading of 6-11-13 is an extraordinary approximation to the formula of 6-11-12 discussed above.

A Figurine Whistle Representing a Ball Game Player

J. Eric S. Thompson

The pottery figurine whistle here illustrated was found somewhere in the vicinity of Icaiche, Quintana Roo, Mexico, by a former inhabitant of that now abandoned village. The finder, a shaman, subsequently moved to Kaxil Uinic and thence to San Jose, British Honduras, taking the figurine whistle with him. In 1931, when I saw it in his hut at San Jose, he was very reluctant to part with it, setting the impossible figure of twenty-five dollars as his final price. This high valuation was due to the fact that the figurine was endowed with great power in effecting cures. The owner customarily burned copal incense before it and sprinkled it with rum when he was engaged in curing ceremonies.

Archaeological specimens which portray human figures, particularly stelae and incense burners, are generally regarded by the present-day Maya as malevolent. It is therefore somewhat surprising to find a benevolent status attributed to this figurine. I did not inquire closely into the activities of the owner, who may have indulged in some black magic and on those occasions employed the figurine whistle. Naturally, such affairs would not be disclosed to a stranger. Five years later the owner parted with the figurine whistle for a trifling sum. In the interval he and other inhabitants of San Jose had been moved to the urban center of Orange Walk, where the atmosphere is less congenial to magical practices, whether white or black.

The figurine whistle (present height 9.3 cm) lacks the top of the headdress and the mouthpiece of the whistle. The latter had been attached at the

25.1. Figurine whistle: (a) front view; (b) profile.

base of the back, and presumably was of the hog-snout type prevalent almost throughout British Honduras and the Peten. There are two finger holes in the back at shoulder level. The clay is a darkish brown and unslipped, but with traces of what may be white paint (alternatively lime incrustation) in the groove of the belt and around the bracelet. The figure appears to have been cast in a mold, and presumably belongs to the Tepeu horizon of the Initial Series period.

In view of the ball tucked under one arm and the heavy belt (Thompson 1941) I think there can

be little doubt that a ball-game player is portrayed. What appears to be the leathern hip cloth projects below the belt on each side of the narrow *maxtlatl* (loincloth). A queer arrangement is attached to the left side of the belt or hangs from the wrist of the arm above it. Could this be the glove dangling empty from the wrist? The detail of the left hand is

not sufficiently clear to indicate whether a glove was worn; the right hand certainly is ungloved. There is no kneepad visible, presumably because of the vestigial treatment of the legs.

The nearest reported ball court to Icaiche is that at the Initial Series period site of El Palmar, Quintana Roo.

Notes on a West Coast Survival of the Ancient Mexican Ball Game

Isabel Kelly

These notes were obtained in the spring of 1939, during an archaeological survey of the west coast of Mexico. Originally I planned to publish them jointly with Mr. Carlos Linga, who, through his commercial agents in southern Sinaloa, has acquired several accounts of the same ball game from the Mazatlan district, but as this has not been feasible, my Nayarit data are recorded here, without benefit of his somewhat fuller information. The account comes chiefly from Valentin Zamorano, a former player and a manufacturer of balls, with a few supplementary details from his son, Basilio Zamorano. In former times this family was among the rubber workers who supplied balls to the stretch of coast between Acaponeta and Culiacan (Sinaloa), at a price ranging from 25 to 60 pesos.

The game, called *hulama*, was current in the Acaponeta valley, Nayarit, until about 1930. It is said still to be played occasionally in the hills and in small villages, particularly on the feast days of San Juan, San Pedro, and Santiago, and on Sundays and the Saturday of Easter week.

The ball (*hule*, rubber) was round end of solid rubber. The standard circumference was three finger spans plus three fingers; the weight, 3 kilos, 600 grams. A specimen (3-7565 in the Museum of Anthropology, University of California, Berkeley) purchased from Bernabe Diaz, in the nearby ranch of Camalotita, is undersized and in poor condition from having become flattened during storage. The diameter ranges from 163 to 196 mm, with an average of 180 mm.

Rubber was obtained from the low coastal country immediately south of Acaponeta, and particularly from Pozo de Higuera and Huaritupa. The gatherer climbed the tree and, with a machete, notched the trunk its full length. A leaf of *aguama* (*Bromelia* sp.), stripped of the edge spines, was placed against the wound to carry the latex to a corked vessel. A five-gallon tin of rubber latex was sufficient for making one and a half balls.

To coagulate the latex, the root of the *machaquana* [*Operculina rhodocalyx* (Gray) Stardl.] was diced and added to water. For this identification I am indebted to Dr. Paul Standley, of the Field Museum of Natural History. Dr. Standley writes that the moonvine, which likewise is a morning glory, frequently is used to coagulate rubber. Prof. Maximino Martinez (1928:24) notes the use of the juice of *Ipomoea bona nox*. The solution was then strained into the latex, three parts solution to one of latex. A small quantity of this mixture was heated to luke-warm, tested with a small pointed stick, and, when of the proper consistency, removed from the fire. The rubber adhering to the shaped into a pellet, which was pressed against the knee and from which the rod was withdrawn. The ball was thus built up, layer by layer, as small quantities of rubber were added to the pellet-like nucleus. After each increment of rubber was squeezed free of the liquid, the ball was shaped on a flat board held slanting against the knees to let the liquid run off. From time to time the growing ball was shaken vigorously beside the ear to detect any remaining liquid, which was pressed out through

a

b

the blister perforated with a small stick. When perfectly round, the finished ball was smoothed and polished with a stick.

After each game the ball was washed and dried thoroughly, suspended in a bag so as to hang freely, and turned frequently lest it become flattened. A well cared for ball lasts about six years. Although the purchased specimen mentioned above is old and neglected, it bounces waist-high when dropped to the ground.

Players were barefoot and ordinarily naked save for a breechcloth and a special belt or shield, called *chimal*. The latter generally was made of the root fiber of the *chamate* (*Ficus* sp.), a fig with aerial roots. A length of root, about 2.5 m long, was cut, steeped in water, and beaten with a stick to remove the outer bark. The remaining fiber was opened and spread in the sun to dry. The belt was not woven; a model made by Basilio Zamorano consisted merely of a strip of thick bark, 1.5 m long and 15 cm wide.

This particular example, however, is not from the *chamate* but the *haba* (*Hura* sp.). Valentin Zamorano described the belt as about 10 cm wide and laced in the front with leather thongs. The lacing was drawn tight by two men until the player felt "light." Within the belt was a protective pad of leather or, more recently, a section of automobile tire, to soften the blow of the ball. Also in keeping with modern trends is the report that drill or canvas might be substituted for the bark fiber.

The game was played on a court (*taste*), long and narrow, "like a street," Valentin Zamorano described it as 105 pasos or 3 varas wide by 15 varas long. The informal measure of *paso*, as used on the west coast, consists of two short paces, totaling a little over 1.5 m. A *vara* is roughly the equivalent of a yard (actually, 2.78 ft.). It may be assumed, therefore, that the court was roughly between 2.25 and 2.80 m wide. It was simply a rectangle marked on the ground, with no walls or other permanent construction. Stone or

brick marked the four corners, with one marker at the center of either side line to indicate the central transverse line. Three single markers, indicating respectively the two end lines and the central line, were not used. Stakes might serve as markers but, to avoid injury to players, they were set flush with the surface of the court. The outline of the court and the transverse line across the center (which invariably extended well beyond the sidelines) were drawn about 10 cm wide in the dirt with the foot. The center line was called *analco*; the zone behind either end line, *chiche*. According to Cecilio A. Robelo (1900:43), *analco* has come to mean "from the other side, on the other shore of a river." Jose Maria Arreola (1935:6) gives the same meaning.

The number of players varied. There might be but one on either side, but generally a team consisted of from two to five. If there were five, one of each team was stationed at the center line, with the remaining players of his side strung diagonally behind him, so as to cover their half of the court most effectively. The rear-most player of each team remained at his station by the back line; he was called the *golpeador*, 'striker'. Other players seem not to have had names.

At the beginning of the game an umpire (*juez*), or two, one for each team, stood at the center line. He started the play by rolling the ball into the court. It was recovered (in the hands) by any player who happened to be near. He then threw the ball swiftly (again, with the hands) into the court of the opposing team. One of the latter returned it, either at full, volley or on the bounce; he was required to receive it either on the hip or on the thigh, to within four fingers' distance of the knee. Disputes were settled by examining the welt left on the body. If the ball hit outside the acceptable hip-thigh zone, or if it were riot returned to the other courts a point was scored for the opposing team. Apparently the ball need not be returned on the first bounce. A player fell to the ground to receive a low ball and leapt in the air for a high one. He could receive on either hip, according to personal preference, but a given player always used the same hips. In the accompanying photographs a lad of Camalotita obligingly gives an impromptu demonstration. In Figure 25.1a, he awaits the ball; in Figure 25.1b, he has just struck it. It need scarcely be remarked that the game was dangerous. If the player misjudged by a few centimeters, he received a heavy, moving body in the solar plexus. Injuries frequently were fatal.

It is said that if the ball were received initially by the center player and if the latter did not touch the central line with any part of his body, his team had the right to invade the territory of the opponents.

The advantage of such an invasion is not understandable unless the end lines functioned as goals. Basilio Zamorano stated that if the ball hit within the court and bounced over the back line without being returned, a point was scored for the attacking team. But this is simply another way of saying that a ball which hit within the proper court and was not returned scored a point for the opposing team. Neither of the Acaponeta informants appeared to regard the end lines of any particular significance in scoring, although they were questioned specifically concerning this detail. In so far as I could determine, scoring was exclusively by means of fouls or failures made by the opposing team: by failure to return the ball by means of the hip-thigh blow; by having the ball fall in one's own court; or by knocking the ball out of bounds. A ball which fell out side the court, without first having bounced within, was called *muerta* (dead). The earlier accounts which were sent to Mr. Linga from southern Sinaloa indicated a scoring basically similar to that just described. He tells me, however, that in a later account the end lines do function as goals. It may be assumed that my data, as well as Mr. Linga's earlier information, should stand corrected.

The ball remained in the possession of the team which scored. Succeeding plays were started according to the number of points held by the team in possession of the ball. These may be outlined thus:

Una: The ball was put into action by the *golpeador* of the team which scored on the opening play. He bounced the ball one to three times, touched it to his hip, and threw it into the air (with the hand) so that it would fall into the opposing court. As the ball left his hand, he called "*una*."

Dos: If we assume that the same team scored on the play just described, the same *golpeador* again opened the play. He rolled the ball swiftly along the ground into the opponent's court, calling "*dos*."

Other plays were started according to the same pattern: *una*, *cuatro*, and *cinco* (1, 4, 5) being thrown overhead (*arriba*); *dos*, *tres*, *seis*, and *siete* (2, 3, 6, 7) being rolled on the ground (*abajo*). At each play the *golpeador* called the appropriate number as the ball went into action. J. Eric S. Thompson suggests that actually the *golpeador* called the score (*raya*) of his team rather than any number of play. This seems entirely plausible since, as stated above, the mode of patting the ball into action was determined by the number of points held by the team in possession of the ball. In any case, the initial play, followed by the 7 specified above, would account for a total of eight, which number of points presumably constituted a

game. Rolled plays (*abajo*) were called *male*; over-head plays (*arriba, en viento*) had no special name.

Ordinary progression of score was relatively simple. A team which won a play gained a point and one which lost a play relinquished a point. In other words, the scoring was double and that of both teams changed on a single play. After each play the ball was held by the scoring side. There were, however, some exceptions and ramifications, a number of which remain entirely obscure. For example, it was said that if a team had three points and lost one, it had the privilege of putting next play into action *abajo*. This is not clear, for a team which to a point presumably would not have the ball at the start of the succeeding play. Moreover, it was said that a team holding two points, but which then lost one, might start the next play by calling for 3. The same difficulty applies here. However, this would appear to be a means of giving a team a gambling chance, that of gaining the score of three or of losing all. Unfortunately, these complexities of scoring could not be disentangled because of linguistic handicaps, and it is hoped that when Mr. Linga publishes his Sinaloan data many of these obscure points will be clarified. If a team held either three or seven points it stood to lose all. If a team with three points permitted its opponents to gain two consecutive scores, then instead of losing two points, it yielded all three. So also, if a team had seven points and the opponents scored four times successively, the losing side relinquished all seven points, while the opponents gained four points and retained the ball. The above conditions were called *urde de tres* and *urde de siete*. The same situation may have held for the score of six, as well as for three and seven, for mention was made of *urde de seis*, said to obtain when a team with six points lost four consecutive plays. It may be noted that the *urde* applies exclusively to the *abajo* plays, but of these, Score 2 is exempt.

A game generally lasted from about 4 o'clock until dark, without rest periods. With good players a game might have to be continued three or four days, being resumed at the score of the previous afternoon. The implication is that a score of eight constituted the game, but Basilio Zamorano thought that a game could be played for any number of points arranged at the start. If, as has been suggested, above, the present data are faulty and the end lines actually served as goals, presumably the passing of the ball across the opponents' back line would terminate the game.

The modern version of the ball game at Acaponeta appears to have been entirely secular, except for the fact that religious feast days were favored for play. No mention was made of intervillage or inter-group

competition, but such rivalry may well have existed. A team was organized by an interested individual who might or might not function as umpire. He was called the "owner of the game" and apparently fed the players and supervised practice. Players were expected to train conscientiously, and an inattentive one might be whipped by the organizer. Training fare was normal, though supervised, until the day of the game, when diet was restricted to liquids, especially milk; but if the game was continued another day, solid food was eaten. Players were expected not to leave the house, to abstain from sexual intercourse, and to bathe immediately following a game. The organizer and financial backer apparently received his compensation in the attendant prestige and in winning bets. Heavy gambling invariably accompanied the ball game, and in this the women participated. A losing team gained nothing but "*puros golpes*" (just blows).

The above data presented a number of interesting points. Although the account manifestly is incomplete, it is at least definite and, in parts, detailed. Obviously, the modern game of Nayarit and Sinaloa is far from identical with that recorded for the high cultures of central and southern Mexico. But, at the same time, a genetic relationship is implied: both games involve corridor-like courts, a ball of solid rubber, the obligation to strike with the hip or thigh, and an accompaniment of lavish betting.

Unfortunately, the early accounts of the game, both in the Mexican and Maya areas, are so vague that little is known of the manner of play. Fundamentally it was probably not unlike that I have described, although undoubtedly it was much more complex. Masonry walls against which the ball must have bounced, elaborate I-shaped courts, wall rings; these and other traits all indicate a more elaborate ensemble. Probably this west coast occurrence should be regarded as a modern, peripheral survival either of an archaic form or of a simplified version of the classical game. In any case, it would appear that the chief hope of expanding knowledge concerning this famous Mexican-Maya institution is through study of the modern survival, the genetically related, albeit simpler, game of the west coast. It is noteworthy that such a survival should be found in a straight mestizo rather than in an indigenous milieu.

The distribution of the Sinaloa-Nayarit game is imperfectly known, but has been established definitely as far north as the Rio Fuerte (Beals 1932:188) [quoting Perez de Ribas]. Dr. Gordon Ekholm was told that the ball game still is played at Bacubirito, on the Rio Sinaloa, and at Mocorito. Dr. Beals writes me (June 8, 1940) that a similar game is reported for the Cahita; he suspects that it may not have been

general among them, but may have been confined to the Rio Sinaloa area. He mentions another modern game which may be an offshoot of the one under consideration. It is played with a small rubber ball, batted against the right forearm, on which a protective guard is worn. It is a foul if the ball touches any other part of the body. This game is specifically reported in Guasave, Nio, Bamoa, Tamazula, and Mocorito. The southern limits of the coastal distribution of *hulama* are not known below Acaponeta, in northern Nayarit. There are no data from the Jalisco littoral, although the game is known in Teocaltiche, in the old Caxcana province, along the modern Jalisco-Zacatecas border (*Noticias* 1878:357).

In view of the informal court herein described for modern Nayarit, it is evident that this, or a similar, ball game may have flourished in an area without having left any perceptible archaeological trace. Perhaps for this reason, there is no mention of prepared ball courts from the west coast of Mexico, from northern Sonora to the Colima-Michoacan frontier. The Sonoran court, said to be of the "Arizona type," was located during an archaeological survey by Dr. Gordon Ekholm, who placed it a few miles south of Santa Cruz, Sonora, on a mesa above the river. The Colima-Michoacan court is at Puente de Cerritos, in the Coahuayana valley, and has been dubiously identified from surface evidence alone. It consists of a long, narrow plaza enclosed by four low mounds, 1–1.5 m high. The end mounds are broader and slightly lower than the side mounds, which are long, narrow, and their surfaces cobble-strewn. In profile the side mounds are sharply peaked, and their upper surface averages less than 1 m in width, obviously too narrow to have served as a house foundation. Moreover, the floor of the "court" is flat and at a slightly higher level than the surrounding plain. The whole, from the floor to the mounds, appears from surface indications to be an artificial structure.

The historical and modern occurrences of the ball game in northern Nayarit and virtually throughout

Sinaloa suggest a former continuous or nearly continuous distribution into the American Southwest where, in recent years, a number of ball courts have been recognized and excavated. Although the modern version of the game may explain the apparent lack of prepared courts on the west coast, it by no means explains the reappearance of such courts in the Southwest. It is unlikely that the Arizona Hohokam and their neighbors would have gone to the tremendous effort of building ball courts unless the latter were an integral feature of the game as it was adopted by them. Thus, despite the suggestion of a nearly continuous distribution, it seems probable that the west coast can not be regarded as the potential source of the Southwestern game.

Archaeologically the west coast of Mexico still is little known, and it is possible that ball courts have hitherto escaped notice but will be found in the course of more intensive investigations. In northern Nayarit there are repeated rumors of stone ball courts in the adjacent sierra. These reports were not localized and time did not permit a search. Furthermore, ball courts have been reported in the nearby Sierra Madre of Durango by J. Alden Mason (1937). The Teocaltiche account noted above establishes the game as current in the Caxcana during the late sixteenth century.

As far as present information goes, there is no demonstrable evidence of Hohokam–west coast interplay in any sphere of culture, either ball courts or otherwise. Some inland route of contact, therefore, must be sought. It may be noted that, in addition to ball courts, pseudo-cloisonné painting is common to the Hohokam and the western highlands. Both ball courts and inlay painting are well dated in the Southwest, and occurrences in the western highlands should be examined, for both distribution and chronology. It may well be that the occupation of the western highlands, like that of the west coast, will prove to have been far too recent to have bearing on the comparatively early Hohokam occurrences.

Animal-Head Feet and a Bark-Beater in the Middle Usumacinta Region

Linton Satterthwaite Jr.

UNIVERSITY MUSEUM, UNIVERSITY OF PENNSYLVANIA

The accompanying photograph is recorded because J.E.S. Thompson (1943) has recently noted that "The Mexican period . . . is poorly developed in the Central Area," and has used "tripod dishes with feet shaped as heads of animals or persons" as a criterion of the Mexican period. If animal-head feet are a proper criterion of the Mexican period, I think the pictured bowl is good evidence, hardly conclusive, for existence of Mexican-period high culture in the Middle Usumacinta part of the central area.

In 1934 the following photograph-note, including information from the storekeeper, was made at Las Escondidas: "Tripod bowl with animal effigy feet, and bark beater. In possession of Don Casimiro Algara at his bodega at Las Escondidas, opposite Desempeño. Reported as being found at ruins two or three kilometers from his lumber camp Samaneo, which is supposed to be only two leagues from Piedras Negras, on the Chiapas side of the river. To be reached from Porvenir if river is crossable." Sketches and notes show that the bowl is perfectly flat-bottomed, with a tendency to bulge up in the center; it has straight flaring sides and a noticeable lip (diameter 39.5 cm; height 13 cm, of which 6 cm are the feet). In the back of one foot, which rattled, was a small tear-shaped slit. Probably all the feet were of this type. The mouth of the animal, supposedly an armadillo, is incised; the ears "seemed" to be applied. I do not remember whether or not the dull polished reddish orange inside and out covers the feet. The slightly oval, limestone bark-beater (diameters 8 and 8.5 cm, thickness 4 cm) has 12 grooves, 2–3 mm

wide, on one flat side and 17 on the other. The deep hafting groove, which fails by 2 cm to encircle the beater, is about 7 mm deep and 14 mm wide.

Casimiro Algara and his son, Jose, who had been lumbering only in this neighborhood and not farther up or down the river, would never have brought any find of this sort south from Tenosique. I think I confirmed my information with one or the other when they later passed through Piedras Negras, because I subsequently recorded that the dish and stone implement were seen at Las Escondidas but brought from Samaneo by Don Casimiro. Likely a workman made the discovery, about which the Algaras, now dead, knew none of the details.

This bowl probably came from La Mar or Bud-silha (see map in Maler 1901–1903) unless its provenience is some unrecorded site (conceivably of Mexican period in architectural type). Stela 1 at La Mar and Throne 1 at Piedras Negras are placed by Morley (1938) without question at 9.17.15.0.0. Other monuments at Piedras Negras carry Morley's sure readings there to 9.19.0.0.0. The Samaneo bowl could be considered a modification of Robert E. Smith's Tepeu form, "red ware tripod plate with flaring sides" (Preliminary Shape Analysis, Fig. 18), which has a different type of foot, a very slightly curved instead of straight side, and no lip. A still closer approach can be seen at Piedras Negras, where the feet are solid and the flaring sides almost exactly straight (Cresson 1937, Fig. 26). Flat-bottomed bowls and plates, tripod or not, are characteristic of the latest deposits at Piedras Negras. The bottoms usually but

27.1. Tripod bowl and bark-beater; former found in vicinity of Samaneo, Chiapas.

not always curve up toward the center, if the vessel is large. The position of the animal-head feet is straight down on the specimen illustrated here and resembles that of pointed rattle feet, and in fact that of all feet shown in Cresson's plates for Piedras Negras. In the southern area the animal heads may be at an angle (Butler 1940, Fig. 24h).

We may conclude that the Samaneo vessel dates from the Tepeu ceramic phase of the Initial Series period or later; and that it might have been produced locally, reflecting outside influences. For what it may mean I call attention to occurrence at Piedras Negras of what seem to be feet in form of more or less complete animals (Cresson 1937, Fig. 48). But I am sure that those are very few and probably trade objects.

Piedras Negras and neighboring sites were undoubtedly on a trade route, mostly by water, leading southeast to the Alta Verapaz, northwest to Jonuta, thence to either Veracruz or the borders of Yucatan (Satterthwaite 1943). Full publication of Piedras Negras ceramics will undoubtedly show late trade relations with the Alta Verapaz region (carved, untempered orange identities in form and design, probably in paste) and at least close correspondence with Jonuta in late form and incised design. The stage is thus set for Mexican influences to operate here, from either direction, at the close of the local Initial Series period. It is also set for an importation of the Samaneo bowl, at least as far as the feet are concerned. Compare its feet, and Cresson's (1937) Figure 5 with feet at Isla de Sacrificios, found by Miguel Angel Fernandez and Wilfrido du Solier (Fig. 14.9i-k, n).

If our vessel had been found broken, one might suppose it was discarded by Mexican-period traders

traversing an abandoned high-culture area. But since it is complete and still retains some polish, even as a trade piece it much have been received by local inhabitants who had a use for it and who eventually carefully buried it. It is not a "utilitarian" type, nor is it a censer, a class of pottery the manufacture of which probably survived abandonment of the architectural centers. Since it was found in a group of ruins, the rebuttable presumption is that buildings also were still in active use.

So, trade piece or not, I think this bowl is good evidence, though; not conclusive, that the theocratic organization responsible for Middle Usumacinta Maya sites survived to receive outside objects or influences during the Mexican period. If this is so, either the Mexican period (or at least the concept of animal-head feet) goes back to about the end of Cycle 9, thus overlapping the latest surviving Initial Series monuments in the middle of the central Maya area, or the Usumacinta sites were not abandoned when local carving of Initial Series monuments seems to have ceased, at or before the end of Cycle 9.

As a confirming circumstance I record a single tiny thin white sherd of what was presumably a marble or onyx vessel at Piedras Negras (Cat. L-39-250). It had been washed into a covered drain from its open end, along with a sherd of a flat-bottomed, flaring-sided bowl. Its presence suggests late trade relations with the Gulf Coast region or farther afield. At San Jose, Thompson found the marble vase only in San Jose V, and in his 11.16.0.0 scheme the start of that period is tentatively, placed well after the latest Piedras Negras dates (Thompson 1939, Table 17). With the alternative scheme, such reasoning as to Long Count date would not apply.

New Photographs and the Date of Stela 14, Piedras Negras

Linton Satterthwaite Jr.

UNIVERSITY MUSEUM, UNIVERSITY OF PENNSYLVANIA

Drawings of eroded inscriptions must, I think, be accepted as representing the possibly fallible judgment of the person who made them. While one may have confidence that the drawings of a given epigrapher are generally correct representations of what the Maya originally carved, if he proposes to make important deductions from a particular drawn detail, perhaps he should be careful to make it clear that the deduction is no better than the source and so subject to the same possibility of doubt. When it is possible to re-examine the stone itself, or otherwise confirm or correct the element of judgment in the drawing, it would seem wise to do so, and thus found the deductions on a record in which the human element has been reduced to the minimum possible.

J. Eric S. Thompson has recently proposed abandonment of Teeple's reading of the date on Stela 14, Piedras Negras, which was 9.18.0.3.1 7 Imix 19 Pax, 2 moons 26 days. Without taking the above precautions he proposes instead 9.16.6.17.1 7 Imix 19 Uo, 5 moons 26 days (no. 18 in this series). It happens that Stela 14 from Piedras Negras is now in the University of Pennsylvania Museum on loan from the Guatemala Government, along with Stelae 12, 13, and 40, Lintels 3 and 12, one leg of Altar 4, Throne 1, and Miscellaneous Sculptured Stone 16. Inquiries respecting these are always welcome, casts of doubtful portions can be ordered, and a series of photographs especially lighted to bring out glyphic details have been made by the museum photographer, Reuben Goldberg. These may be ordered by anyone, with permission to reproduce.

In Figures 28.1 and 28.2 are two pairs of these photographs showing the Stela 14 inscription, the left side of each pair lighted from below, the right from above. I shall use them in attempting to show where Thompson might easily have fortified his new reading, and where, I think, they suggest doubt.

The previously published sources for this inscription are Morley's drawing and photograph (Morley 1938: 5, pls. 39j, 141d). Another Morley photograph (Cat. 29-1-31) is on file here, and presumably was available to Thompson.

Thompson deduced that the kin coefficient of the Initial Series was 1, because the day reached was recorded as Imix. He seemed, when he wrote, to agree with Morley that the kin number could be either 1 or 8, considering the head numeral alone. One of our photographs shows rather more clearly than the published one that the forehead element probably consisted of two-parts. This is also fairly clear in the unpublished Morley one. On seeing ours, Thompson called my attention to the preferable reading of 1, by inspection alone. Morley's drawing is thus confirmed, and there is little need to derive the 1 kin; from the Imix.

In stating positively that the day is 7 Imix, Thompson probably relied on Morley's drawing; at least, to my eye, Imix elements in the Morley photographs were doubtful until I had studied the better photographs here supplied. Now, I can see faintly, as I shift from one to another view, the expected large circlet on the top, one of the line of tiny circlets below this, and two of the pendent lines. Morley's

judgment in drawing Imix is thus also confirmed, though he evidently reconstructed most of the glyph.

His drawing of the month coefficient, in which the three lower dots are evenly spaced, is reconstruction, as examination of the stone itself and, less satisfactorily, of our photographs, shows. There are three humps below a large hole, the two upper humps closer together; and the space between them is not so deep as that between this upper pair and the lowest hump. From inspection alone the upper pair might possibly be an eroded long crescent, though placed too high, or what remains of a long sign between two dots at the extremities, such as are common at Piedras Negras. A reconstruction of 17 instead of 19 appears a possibility as far as the remains of the coefficient itself are concerned. To avoid circular reasoning I think Thompson's flat statement that the coefficient is 19 should be amended by adding "because by inspection the kin sign is probably 19 surely 1 or 8, and the day sign almost certainly Iran." One king Imix, would require four dots in the month coefficient; 8 kins, Lamat, would require one dot, not two. But the condition of the stone does not justify reasoning in the other direction, to remove any lingering doubts as to the head for 1 and the Imix sign.

Thompson calls my attention to further confirmations of his readings. It is row clearer than before that the superfix, of the month coefficient is not that of Pax, as required by Teeple; and that there is a line looping down under the eye of the uinal coefficients.

So far our photographs confirm Thompson's new reading of the Initial Series date by making it clearly unnecessary to rely on the drawing, and by adding certain details not available in either the drawing or the published photograph. It appears to me that the new reading is almost certainly correct.

Yet implicit in the new reading is an assumption that the Maya recorded a wrong moon number, or else, in the midst of the period of uniform moon numbers, recorded one in a nonuniformity system. Thompson said that "Glyph C appears to record two moons, but Glyph X is of a form found with 4C or 5C." A Maya mistake is thus implied, because of the Glyph X form; and a wrong moon number may just as well be corrected to 5 (required at the new Initial Series date) as to 4. But if the record is 4, Glyph X gives no independent support for changing to the required 5. Morley's main drawing and another (of this coefficient only) in his text do not agree with each other, and put one on notice that doubt of the reading 2C may properly exist; in Morley's mind 3

28.1. Stela 14, Piedras Negras: left side, upper part (scale in centimeters).

seems to have been an alternative which he eliminated. Our photographs support to a certain extent what an examination of the stone convinces me is so. There are two humps at the bottom close to each other, which might be an eroded crescent; the space between them is not so deep as between them and the two dots above. Yet I think a reading of four dots is a reasonable possibility, if unequal spacing was tolerated, as apparently it was in the month coefficient. If we consider the lunar glyphs alone, a reading of 4C, with its proper Glyph X form, is indicated, as one would then seek an Initial Series-value outside the limits of the period of Glyph C uniformity. So Glyph X does not surely support the new Initial

28.2. Stela 14, Piedras Negras: left side, lower part (scale in centimeters).

Series reading by certainly requiring some change in the C coefficient. It merely permits the required change to be made.

Finally, I come to the moon age, which has no bearing on the Initial Series value, except within unsettled limits. Thompson stated flatly that it is recorded as 26, presumably depending on Morley's drawing or the unpublished photograph, the latter of which also seems to indicate crescents above and below a central dot. This effect can still be obtained by proper lighting, so the stone has not changed since Morley's drawing was made. The effect is produced by shadow on a fractured surface (top element) and on a badly worn or fractured surface (bottom element). Our photographs show clearly enough that the upper element may be a fractured dot; for neither element is there certain indication of original crescents. The moon age may therefore have been either 26 or 28, as far as inspection goes.

Thompson says the age "corresponding to" his Initial Series reading is 6E or 7E (i.e., 26 or 27) without indicating his method of calculation. He advises me that he uses the Teeple Palenque formula 6.11.12 and 29.53059 from the nearest base. A permissible alternative method is to figure the true change since the double age record at 9.12.2.0.16, taking the 27 days recorded for this date on Stela 3 as in step with Maya lunar calculation. The true average lunation change (at 29.53059 days per lunation) between that date and the new Stela 14 reading is .83935, rather close to a full day. Hence an average Maya calculation would tend to raise the Stela 3 age of 27 to age 28 here, though observation or peculiarities of a whole-day prediction calendar might lower it to 26. I cannot see that we have any present basis for choosing between 26 and 28, and submit that either is a possibility.

Grooved Stone Axes from Central America

A. V. Kidder

It has commonly been supposed, although I can find no statement to that effect in print, that grooved stone axes do not occur in Central America. It therefore seems desirable to record six specimens from that region which have recently come to notice; four from Guatemala, one from Nicaragua, and one from Costa Rica. There is no doubt as to the authenticity of these objects, or as to their approximate provenience, but data are lacking as to the circumstances of their discovery and as to associated finds. Their age is accordingly a matter of conjecture.

All four Guatemala axes (Fig. 29.1a, b, c) are of admirable workmanship. They are characterized by a laterally flattened, comical poll; full (as distinguished from three-quarter) groove, encircled above and below by low ridges; and blade whose converging sides round off to a slightly curving edge at right angles to the long axis of the implement. The only one of these specimens which I have been able personally to examine was purchased by Mr. Neil M. Judd at Chichicastenango in 1914 and is now in the United States National Museum (Cat. no. 284130). It is of greenish black stone; all surfaces are well smoothed, although traces of the pecking done in bringing it to shape appear in the groove and on one face just below the lower encircling ridge; length 10.5 cm, greatest thickness (at the ridges) 3.8 cm.

Of the two axes shown in Figure 29.1b, c, the larger is in the collection of Mrs. Gordon Smith. It was found on her Finca Moca, Dept. of Suchitepequez, several years ago. It is 17.6 cm long, 6.2 cm in greatest thickness. The smaller, for the photograph

of which I am indebted to Mr. Owen Smith, who also made available that of his mother's specimen, was found on Mr. Guthrie's Finca Adelaida, less than 10 km from Moca. Its length is 10.4 cm, greatest thickness 4.3 cm. The fourth axe, of which I have seen only a small photograph taken by Dr. J. A. Mason in 1930, is closely similar in shape to the other three. It is in the collection of Sr. Vitalino Robles and is said to have been found at Tinhuinlinhuitz, southwest of Quetzaltenango.

The axes from Nicaragua and Costa Rica differ strongly from the Guatemala examples. The former (Fig. 29.1d), in the collection of M. Margoux, Belgian Consul at Managua, is said to have come from near that city. It is of light gray stone heavily mottled with black. It has a shallow, full groove, small rounded poll, and wide blade with curved edge. The blade is well polished; the groove is smooth but unpolished and bears faint encircling striations; the poll is partly left in the waterworn surface of the pebble from which the axe was made, partly pecked and left unpolished. Length 13.5 cm, greatest thickness (just below groove) 4 cm. The Costa Rica specimen, in the National Museum at San Jose (Cat. no. 3323), is attributed to the Nicoya Peninsula. In size and shape it is almost a duplicate of the one from Nicaragua.

While it is conceivable, though because of their close similarity I think it unlikely, that the Nicaragua and Costa Rica specimens are, so to speak, "sports," those from Guatemala are so much alike and of so distinctive and specialized a form, that they are

29.1. Grooved stone axes: (a–c) Guatemala; (d) Nicaragua. Length of *d*, 13.5 cm.

obviously the product of a well-established industry, seemingly localized on the Pacific slope south of Lake Atitlan. It is to be hoped that further examples may be found under conditions permitting establish went of their cultural affiliation.

No grooved axes have, so far as I know, been found south of the Mexican state of Mexico, some 500 km to the northwest. Said to be from Tlacotepec, near Toluca, in that state, is a single specimen with full, shallow groove (Starr Collection, Chicago Museum of Natural History, Cat. no. 94858). Linné (1934, Fig. 249) illustrates from Xolalpan what appears originally to have been a celt with a very shallow secondary groove pecked about it. These two rather amorphous axes are the only examples of full grooving I have seen from Mexico, except the peculiar effigy forms from Jalisco and Zacatecas (Saville 1928). The standard axe of northern Mexico is three-quarter grooved. The southernmost of these of which I have record are two, attributed to Ahualulco and Etzatlan, Jalisco (Starr Collection, Chicago Museum of Natural History, Cat. nos. 95491, 95500). The

three-quarter grooved axe appears in respectable numbers only still farther north (La Quemada, Zacatecas; specimens in Mexico National Museum; see also Batres 1903, Pl. 19. Sinaloa, Sauer 1930, Fig. 7; Ekholm 1942, Fig. 20). These are presumably allied to the three-quarter grooved axes so common in the Casas Grande area of Chihuahua, and the Middle Gila in Arizona. The full-grooved type reappears in Anasazi sites (Pueblo II the earliest?) of Arizona and New Mexico. The closest parallels to the Guatemala specimens, and geographically the nearest with ridge-bordered groove, are seen in collections from the Mimbres Valley of southern New Mexico (Cosgrove 1932, Pl. 39e).

In view of the vast distance separating Guatemala and the Mimbres, it would seem, unless linking finds should tie made in the intervening territory, that the axes here noted must represent an entirely independent development. It is interesting, in this connection, to note that three-quarter grooved axes were also made in the Diaguite area of northwestern Argentina (Thompson 1936, Fig. 11e).

A Vase from Sanimtaca, Alta Verapaz, Guatemala

Elsie McDougall

Figure 30.1 illustrates the design of a fragmentary vase, the pieces of which were amongst broken pottery of a cache, unearthed in 1927, at the mouth of a cave called Calajau, in a hill of that name. It was situated on, a property, Sanimtaca, in the Chama region of Alta Verapaz. At that time Sanimtaca was owned by Sr. Gustav Helmrich, who for about thirty years had owned and developed properties from his residential one, Finca Samac, just north of Coban and well into the Chama Valley. The cache was discovered by Sr. Hugo Doege, then employed on Sanimtaca, and his companion, Sr. Rudolf Hesse, who, taking shelter in the cave during heavy rain, commenced digging near the fire they had made.

Sr. Hesse's account of the experience, as supplied to me in 1931 following my brief visit to Finca Samac where I had the opportunity to reconstruct and draw the vase now illustrated, included a rough plan of the chambered cave and information that Sr. Doege had been able, then, partially to reconstruct this vase from the pottery fragments. Before 1931, Sr. Helmrich had found fragments of another cylindrical vase, somewhat higher and more fragile than the one which is the subject of this Note. Of this specimen enough remained to make clear the ceremonial character of the decoration, which was incised through cream slip and painted. On the reconstructed portion, the two standing personages, with spectacular headdresses, loincloths with long ends, elaborate ear ornaments, and necklaces faced an object of which the portion included in the reconstructed vessel was covered with curving plumes. In

handling the tray-basket of fragments from the cave, I noted a few pieces of a base and rim of an onyx or a marble vessel with carved design, a type represented by onyx vases from Isla de Sacrificios, Veracruz, and similar translucent marble vessels from Ulua Valley, Honduras. However, as sherds were collected from elsewhere in the cave, the association of these fragments with the vessel illustrated is not certain.

Sr. Helmrich, familiar with historical records of the peoples of the Alta Verapaz territory, told me that an important ancient trail through that region and Peten passed over the Calajau hill. Worship practices, of which vestiges have been recently recorded, included propitiation of recognized tutelary deities of certain hills and caves, so that possibly the pottery interred at the Calajau cave may have been an offering to the god of the hill or to the protector of travelers spending the night in what could be the haunt of a feared beast.

Description of the technique of the vase in Figure 30.1 depends largely on brief remarks penciled at the time I made the drawing. The walls of the cylinder were 23 cm high and about 0.6 cm thick. The base was flat. The two deities and their adjacent columns of glyphs were molded or carved, the lowering of the ground to panel form contributing to the salience of the four units, whereas the remaining portion of the cylinder walls provided frames for the panels. The rounded relief was slipped with fine white clay, elaborated with incised lines, and highly polished. The ground color of the panels appears to have been a dull red, apparently slipped. The rectangular frames

30.1. Design on vase from Sanimtaca, Alta Verapaz.

enclosing the figures were a creamy buff, presumably a slip; those around the glyph columns were slipped an orange-red. The terra-cotta color, of which there were traces on the bands at top and bottom of the vase, may also represent application of a slip. The terra-cotta of the base was unpolished, and may represent the natural color of the clay.

Traces of turquoise blue paint on the frames of the two large panels indicate supplementary decoration after firing and, possibly, service of the vase. Some trace of paint, bright red, was also perceptible on the white slip of the relief figures. This, too, is presumably a post-firing addition. Although polychrome slipping, sometimes combined with incised delineation, is represented by perhaps the majority

of straight cylindrical vessels, on which ceremonial scenes are portrayed, from Chama and adjacent region, the combination of polychrome slipping, carving or molding, and post-firing application of paint appears to be rare.

It is possible that the two partially constructed cylindrical vases from the Calajau cave eventually were acquired by Erwin P. Dieseldorff from his close neighbor and compatriot, Sr. Helmrich. If so, they may now be in the Museum für Völkerkunde at Berlin, the repository for many of Dieseldorff's finds; or in the National Museum of Guatemala, to which was presented the large archaeological collection owned by Dieseldorff at the time of his death in 1942.

WOODSTOCK, N.Y.

A Human-Effigy Pottery Figure from Chalchuapa, El Salvador

Stanley H. Boggs

In February 1943 Ing. don Augusto Baratta, Director of the National Museum of El Salvador, and I were informed by Sr. Domingo Mendoza of several antiquities which the latter offered for sale. All specimens had been discovered in the Chalchuapa Archaeological Zone and were subsequently purchased by the Museum.

One of these acquisitions, a hollow, modeled; pottery effigy of a man, affords a valuable addition to our knowledge of ancient art in El Salvador and offers some interesting suggestions regarding late preconquest cultural influences in Central America.

Unfortunately, this effigy was not found by trained excavators; consequently, data on its stratigraphic position are not available. However, I have been able to determine the exact locality from whence it came and hope eventually to establish its true chronological position and its relation to one or another of the cultures represented in the Chalchuapa Zone. To judge from the hole excavated by the pothunters who found it, sherds of this statue were encountered 50–100 cm below the surface near the south side of a long-extinct volcanic crater northeast of the Tazumal Group (Fig. 31.1). No mound appears to be closely associated with the effigy.

As repaired, the statue stands 143 cm high, but there is reason to believe that this measurement did not originally exceed 138 cm. Wall thickness of the head and body varies considerably, that of the former being generally less than 1 cm, the latter in places reaching 1.5 cm.

Head, trunk, legs, and arms were made separately, trunk and arms being joined while the clay was still moist and the junctures reinforced with additional strips of clay. Supposedly this method of joining was applied also to the legs, which probably were united by a clay belt encircling the waist. Since the groin, waist, and right buttock were represented by very few sherds, however, this supposition cannot be proved.

The entire figure was composed of three separate parts (1) lower extremities and waist, (2) upper extremities, trunk and neck, and (3) head. To assemble these, the legs-waist portion was set upright, the lower edge of the trunk was dovetailed into the upper edge of the waist, and finally the head was set on the neck and held in position by a hollow tenon which extended downward from the head to fit into the neck. Maximum height of the lowest portion was 60 cm, of the trunk-neck 59 cm, and of the head (exclusive of its tenon) 18.5 cm.

Only those parts meant to represent skin, hair, or garment accessories were smoothed. The accessories referred to are narrow strips or ribbons encircling calves of the legs, upper arms below the shoulders, and the wrists. All these seem intended to portray cloth, or possibly leather, perhaps used to secure to the body the garment which covers it, and bear laterally what appear representations of bow (?) knots. Sandals are bound to the feet by thongs which pass between the great and second toes and between the third and fourth, thence passing around the ankle to be tied in front. Heels of the sandals appear

31.1. Plan of eastern part of Chalchuapa Archaeological Zone, showing finding-site of pottery statue and location of principal mound groups.

to have been held in place by broad lateral straps which passed between the ankles and the thongs which encircled them, Hair of the head is indicated by a slightly raised and, at the back, a flaring area of smoothed, striated clay. The ear lobes are large loops, which probably once bore earplugs.

Most of the body appears to have been clothed, or perhaps armored, in a rough-surfaced garment secured at the waist by a broad belt (knotted in front?). Feathers or cloth tufts decorating the garment are suggested by the applied projections which cover it. The rather elongate-oval form of

these brings to mind feather-ornamented cloaks pictured in various Aztec codices.

Hair of the head; ears, under jaw, vertical stripes from brow to edge of jaw, hands, feet, sandals and thongs of footgear were dark dull red; the face, dark orange-brown; the garment (or armor), yellow.

The right hand, found intact, forms nearly a perfect circle. Undoubtedly the figure grasped some object round in cross section, perhaps a spear or pole held vertically. No fragments of the left hand were found, or at any rate none were offered for sale.

On top of the head is a small, vertical, fore-aft lug or loop through which runs transversely a small hole about 2 mm in diameter. The function of this lug is somewhat a mystery, for it is doubtful whether the loop could sustain suspension of the body (provided the three sections of the figure could be attached together) and there seems little reason for suspending the head separately. Two other explanations of the purpose of this loop, neither satisfactory in the absence of proof, are: (1) that some sort of headdress or other accessory was attached to the head at this point, or (2) that in some ceremonial it was necessary to portray the removal of an enemy's or a sacrificial victim's head, that by a pantomimic cutting of the neck and a lifting of the head by means of a short cord run through the lug, an actor could demonstrate decapitation symbolically.

It is hardly likely that the red stripes across the eyes represent tear lines since they run from brow to haw. Perhaps they are simply literal representations of the painting on a man's (warrior's) face, or even possibly are meant to show tattoo marks. The lack of teeth seems odd in view of the otherwise careful portraiture. Were wooden, bone, stone or other materials used to imitate teeth, or was this figure intended to represent a moan with teeth knocked out or extracted? No one of these suggestions can, unfortunately, be proved as yet.

As repaired by the Museum staff, this figure is certainly inaccurate in one particular and possibly in a second as well. The first variation from the original is in the addition of a waist and belt, for which no evidence exists. This portion was made in order to join the trunk to the legs so that the original parts could be exhibited. Any reconstruction of this waist area is largely guesswork. In Figure 31.2 I have indicated the effigy as repaired as well as what appears to me a more likely reconstruction. The second possible error is in the shape of the nose. The final third of this feature was missing and may have been depressed at the tip rather than straight, as reconstructed.

As stated above, circumstances of the discovery prevent exact determination of the age and cultural association of this figure. Furthermore, lack of similar

31.2. Pottery human-effigy figure from the Chalchuapa Archaeological Zone: (a) entire figure as reconstructed by Museo Nacional; (b–d) more probable appearance of original figure; (e–g) details of head; (h–j) details of torso; (k) left leg.

large effigies within El Salvador renders impossible at this time any study of distribution of this form of modeling within the country. Nevertheless, fragments of certain features, such as eye, hand, foot, and ear sherds, from what must have been figures similar in style technique if not identical in form, have been found in late debris at Tazumal. Eye and ear sherds from late Tlaloc jars of Campana-San Andres debris also bear a general similarity to these elements of the Chalchuapa statue. Since none of these resemble known Maya works, we must assume that they are the products of some other cultural group.

The Chalchuapa figure is duplicated in almost every particular by an effigy from Coatlinchan, a site lying a short distance east of Lake Texcoco, Mexico, which Saville first described in 1897 (1897) and later (1929:162) identified as Xipe Totec. Both figures closely resemble another, found by Linne (1934, Fig. 113) of much the same height and again identified as Xipe. Henning (1918) also identified as Xipe a stone sculpture from Chalchuapa locally known as the Virgin of Tazumal. The head of the Chalchuapa figure described in this Note is analogous to those from the vicinity of Las Mercedes, Costa Rica (see Lothrop 1926:368-370, Pls. CLXXXVIII, GLXXXIX, b, and Fig. 261).

Only in minor elements does the Chalchuapa effigy vary from the Coatlinchan example, the two appearing so similar that they might have been made by the same person. Vaillant (1939:528) assigns the latter, on stylistic grounds, to the Mazapan culture and has dated the flowering of that civilization to the 13th century.

Lothrop has illustrated a group of pottery heads which I believe analogous to those of the Chalchuapan and Coatlinchan effigies. Differences between the Costa Rican and the Mexican Salvadoran examples exist in that the former are more crudely mod-

eled, possess teeth, sometimes wear conical hats and earplugs, have eyes at least partially open and a nose generally concave or extremely convex. Furthermore, no bodies have been reported with these heads from the south. Lothrop believes that the Costa Rican specimens may pertain to the Guetar civilization and may possibly represent the heads of sacrificed captives.

Because of the size and weight of the Coatlinchan and Chalchuapa effigies, one must suppose them to have been made at or near the sites at which they were found. The great similarity between the two strongly suggests that potters from the same tribe if not from the same town, and at approximately the same time that is, within 50 or 60 years of each other) made these images. If Vaillant is correct in assigning the Coatlinchan example to the Mazapan culture, and in the dating of that civilization, then the Chalchuapa statue can hardly be earlier than A.D. 1300 and may be as late as 1450. An inference which may be drawn from this is that Mazapan potters may have been among the Pipil immigrants to El Salvador, or that some accompanied early Aztec traders. This theoretical traveling of Mazapan peoples is entirely possible from the standpoint of Pipil migration legends but as far as archaeology is concerned must rest for the moment upon very unsatisfactory foundations. Again, the possibility that the Coatlinchan-Chalchuapa style grew out of southern influences, from Costa Rica should not be overlooked. Until a reasonably secure dating and cultural assignment can be made for the Las Mercedes effigies, however, it seems to me safest to suppose that the style is a late import from the north adapted to local skills and, probably, uses in Costa Rica. Further documented finds made between the Valley of Mexico and Costa Rica may furnish us the evidence we now lack.

A Preconquest Tomb on the Cerro del Zapote, El Salvador

Stanley H. Boggs

In November 1943, while engaged in cleaning the grounds immediately north of the National Museum of San Salvador, workmen accidentally discovered a small stone cyst containing a badly decomposed human skeleton and two pottery vessels. Further investigation uncovered a third vessel lying a short distance south of the tomb. Ing. don Augusto Baratta, Director of the Museum, and carefully excavated, measured, and photographed all finds. The ceramic material is at present on display in the Museum.

As may be seen in Figure 32.1, the find was made slightly east of the 1^a Avenida Sur and north of the Museo Nacional, above the right bank of the Rio Acelhuate. This area of the city of San Salvador pertains to the Barrio San Jacinto, a residential ward extending over the Cerro del Zapote, to the Cerro San Jacinto along the southeastern limits of the city proper. While San Salvador itself lies mainly on the relatively flat land of the Valle de las Hamacas, the southern wards encroach on low hills such as the two aforementioned and the Lomas de Candelaria, all of which eminences are northern, flanking members of the Pacific coastal range, in most cases thickly mantled with geologically recent falls of volcanic ash.

During the past twenty-five years, topography of the Cerro del Zapote has been altered fundamentally by modern constructions, terracing, and road building. Consequently, it is impossible at this date to determine the exact relation of the tomb to the original surface. As found, the uppermost stone of the cist lay 57 cm under the surface. A stratum of

humus 30 cm thick covers the flat terrain at this point and overlies a thick layer of white volcanic ash, supposedly the same as that which contained Lothrop's ("Pottery Types and their Sequence in Salvador") "upper level types" of pottery. About the tomb, the ash appeared slightly discolored, as though a small quantity of brown soil had been mixed with it at the time of the interment.

The grave was a remarkably regular rectangle 175 cm long, 50 cm wide. Depth of the tomb, from top to bottom of the stones marking it, varied considerably, scaling downward from 50 cm maximum. The long axis trended northwest-southeast, head of the skeleton lying at the northwest end.

There is no evidence that stone slabs formed a floor for the tomb, nor are the indications clear that a special covering was made. Over the skeleton, a fragmentary metate and several round, waterworn boulders were discovered. These, plus one slab which can hardly have formed part of the side walls, are the only signs of a roof remaining. Burial 2-42 of Tazumal, Mound 1, was somewhat analogous. The corpse was extended on its back with head to the east, and a stone structure was erected over it. Adobe was employed as binding material for the crude boulders of the cairn. Apparently this burial was made after the construction of the mound (see Boggs 1944).

As may be seen in Figure 32.2, flat slabs set upright on end lined the sides as follows: one at each end, four along the northern line, three marking the southern (plus a roughly cut, flat slab of scoria).

32.1. Plan of the Cerro del Zapote showing location of tomb.

Their irregular outlines suggest that they had been used in their natural condition.

Of the skeleton almost nothing remained. Long bones and those of the skull were represented by greenish brown stains in the soil which underlay the tomb. Lack of wisdom teeth and unworn condition of the others suggest a youth. From the position of the teeth relative to the bone stains, it appears probable that the corpse was buried extended on its back, and that the head was slightly elevated so that the face looked toward the southeast.

Grave furniture consisted of two pottery vessels. One, an incised plumbate, annular-based vase (Fig. 32.3a, e), reclined on its side between the head of the skeleton and the northwest end of the grave (Fig. 32.2b, c). This specimen measured 7.4 cm in rim diameter and 24.5 cm in maximum height. It was orange with large, irregular slate-gray and olive splotches. The second vessel, a tripod incised bowl (Fig. 32.3e), lay near the southeast end of the tomb (Figs. 32.2b; 32.3b). It measures 18.7 cm in rim diameter, 0.6–0.8 cm in thickness of side walls and 9.4 cm in maximum height. The feet are hollow knobs. The

surface is polished dark brown to black. Exterior incisions seem to have been made when the surface was hard, while the interior, unpolished except around the rim, bears what appear impressed or indented rather than truly incised lines, imparted probably while the play was still slightly moist.

Not in the grave itself, but in exactly the same discolored ash stratum and at the same level as the tomb, 2.92 m south of its northwest end, a tripod polychrome bowl was found. This specimen possesses a badly eroded, discolored (by smoke?) surface but apparently relates to southern styles of the Nicoya and highland polychromes as described by Lothrop (*Pottery of Costa Rica and Nicaragua*). Rim diameter is 23 cm; height 14.3 cm. There is a red primary slip, with a gray (perhaps originally white) secondary slip bearing black and red design. In places, traces of thin orange paint are found but whether this color formed part of the design or was intended as an orange-over-white slipping (as frequently occurs on Salvador pottery) cannot certainly be stated. The feet, cascabel rattles, are animal-head effigies and resemble most closely pisote heads.

I believe contemporaneity of the tomb furnishings with the separate pottery bowl extremely probable because of the stratigraphic positions of the objects and the character of the soil in which they occurred. That they were deposited shortly after cessation of the eruption which caused the fall of ashes surrounding them also seems likely; a carefully formed tomb would hardly have been made during an eruption, but the slight admixture of extraneous earth in the ash does not imply passage of many years following the cataclysm. Complete vessels, such as those of the Club Internacional and Orlando de Bola collections, were found in what appear caches near the bottom of the latest ash layer in San Salvador. These are not intrusive into the ash layer but seem to have been dropped or left at the place in which they were found when their owners were compelled to flee from the region by the eruption which was taking place at that time. No special care had been taken in placing these objects where they were discovered. The present tomb, however, shows care in arranging the stones, which, bespeaks ample time. Furthermore, as stone of the type of the slabs does not occur within miles of the tomb, they probably had to be sought out and brought from a considerable distance. Finally, an ash fall of several meters would blanket most natural features in this area for a considerable time, possibly concealing the known outcrops of the vicinity for years following the eruption.

There are, however, difficulties inherent in any such hypotheses. To list but two of the most serious:

32.2. Tomb. Slabs represented by hachured areas, pottery by solid black, bones and bone artifacts by stippling: (a) profile along northern side; (b) plan; (c) profile along southern side.

(1) we have no means of determining even approximately the original surface or of establishing the thickness of humus covering this region when the cist was formed; (2) filtration of water from above, bringing with it dust or certain chemicals in solution, may have tinged the white ash in such way that it gives the illusion of disturbance by man.

Many thousands of sherds, as well as numerous complete pottery vessels, have been uncovered in the latest, thick ash deposit in central El Salvador. Supposedly most of these ceramic remains are more or less contemporaneous with the ash inasmuch as the usual finding-site shows such ancient material actually within the stratum, generally at or near the

32.3. Cist and associated objects: **(a)** view from north of northwest end, showing arrangement of Plumbate vessel and some wall stones; **(b)** view from southeast of southeastern half of a tomb, showing sherds of incised tripod bowl, collapsed and upright wall slabs; **(c)** incised tripod bowl; **(d)** tripod polychrome bowl found south of tomb; **(e)** four views of Plumbate vase showing incised band.

bottom of it. Therefore, by dating some types of the pottery, or the eruption itself, we might establish not only in space but also in time the interrelationships of many wares and, by extension, cultures in El Salvador.

The most widely recognized pottery types associated with this ash layer, both near San Salvador and in the western zones of the country, are Maya polychromes which have been found also in Copan and dated there to the Acropolis Period. Longyear (1952, Fig. 29c, d) illustrates polychrome bowls nearly identical with hematite red-and-black-on-orange painted vessels of similar form from the Club Internacional collection, San Salvador. Other polychromes found below Stelae I and M of Copan, dated respectively 9.12.5.0.0 3 Ahau 3 Xul and 9.16.5.0.0 9 Ahau 8 Zotz (see Strömsvik 1941:72, 73 and Figs. 14, 16, 18e, f), present close stylistic similarities of other ceramic specimens from the late ash stratum of San Salvador. Unfortunately, however, there is reason to believe that such types persisted until late preconquest times in El Salvador; consequently, only minute study of technological changes in these painted wares, coupled with stratigraphic excavation of many sites in a wide area, will establish a chronological sequence which will in turn permit accurate dating of either the ash stratum or the associated wares yet unidentified culturally.

As far as the present discovery of plumbate is concerned, we have already pointed out some of the difficulties in verifying the degree of temporal comparison between the tomb and the ash stratum. There further remains to be fixed a foundation in fact for assigning certain styles of plumbate to specific dates. Publication of Miss Anna O. Shepard's researches on this ware should clarify this problem greatly.

Salvador plumbate specimens have come to light almost entirely as the results of pothunters' activities. Nothing is known certainly of the provenience or the manner of occurrence of at least 90 percent of the vessels available for study. Therefore, as far as this country is concerned, there is little accurate evidence on which to base distribution studies of the ware, to place it in time, or to relate it to a specific ethnic group. The seven sites excavated cursorily by competent archaeologists in the entire country to date surely do not furnish sound foundations for final judgments on any of these points. My brief experience in three sites of western El Salvador leads me to the tentative belief that plumbate is rare in "architectural sites," that it is a comparatively late ware (almost certainly following the final heavy fall of ash), and that it is non-Maya. If, as has been contended generally, it was a manufacture of Nahuatl-speaking peoples of the 12th century and later, or may by other evidence be dated eventually to a certain era at least, we may have a second line of investigation along which to proceed in dating the late ash fall. In such an event, then, the aforementioned Maya polychromes might serve as supports for an earliest possible dating of the eruption, the plumbate to limit a latest.

For the present, importance of this cist to Salvador archaeology must rest on the following facts: (1) A special type of tomb adds to our knowledge. Very few burials of any kind have been reported in this area. (2) Plumbate pottery is associated with this style of grave. (3) An easily recognizable polychrome ware, of a decorative technique especially common in Nicaragua and Costa Rica; appears to be associated in time with the tomb. (4) The tomb and the separate polychrome bowl are associated in some way with the latest ash fall of the San Salvador area, either contemporaneous with it, or postdating it slightly.

A Tentative Identification of the Head Variant for Eleven

Heinrich Berlin

In 1942 during the regular season of field work undertaken at Palenque by the Instituto Nacional de Antropología e Historia de Mexico, I had an opportunity to start cleaning House XVIII, where F. Blom (1926–1927, Fig. 135) previously had found on the back wall of the inner room a stucco inscription. During the excavation there appeared about 90 more hieroglyphs, scattered among the debris which filled the room. Unfortunately, heavy rains and lack of workmen made it impossible to clean the room entirely and therefore a few hieroglyphs probably remain buried. These are essential, since the excavated glyphs, although many of them are numerical, do not make sense.

The stucco tablet found by Blom was 3 m long and 2 m high and was decorated with bluish green, painted hieroglyphs and with two or three molded stucco priests, the whole framed in a manner similar to the stucco pillar reliefs in the Palace and the Temple of the Sun. In short, this was a stucco counterpart of the famous tablets of the Temples of the Cross, of the Foliated Cross, and of the Sun at the same site.

Among the newly found hieroglyphs there appeared four times a new type which beyond any doubt is a head variant of a numeral. Reproductions of these four glyph blocks are given in Figure 33.1a–d. Figure 33.1a, was drawn by Miguel Angel Fernandez from the original and Figures 33.1b–d were drawn over enlargements of photos made by me at Palenque. The four glyph blocks consist of two elements: the head variant of a numeral and a calendrical hieroglyph. Let us examine these glyphs first.

The calendrical part of Figure 33.1a, corresponds to a month sign of the Cauac group. I think it is Chen. The lower element is certainly the typical Cauac. The upper element is not the accustomed superfix but must be a rather uncommon variant. Generally the superfix of Chen is the same as that of the month Uo. Now it so happens that below each of the two persons flanking the stairway from the inner court to House A of the Palace the month Uo is carved with precisely the same unaccustomed superfix as in the present case, which fact can be adduced as a proof for our correctly identifying the month as Chen, the more so if one takes into consideration that our present aberrant form is at any rate more similar to the regular Chen superfix than to any other superfix of the Cauac month group.

In Figure 33.1b, the time element is the normal form of the uinal with one dot above it, the whole block thus being a Secondary Series reading for the moment ? kins 1 uinal.

Now in Figure 33.1c we again deal with a month. Apparently it is Kayab. It should be noted that the kan element which generally substitutes for the eye is replaced by a clearly defined eyelid, such as is known to occur, also rarely, in the Kayab hieroglyph. The dots of the beak are not very common but occur, for example, in the Kayab variant of Cab in inscription number 6 of the monumental stairway at Naranjo.

Finally in Figure 33.1d our numeral is associated with a day. The glyph is still partly covered with a clay layer, but the exposed surface shows that it could be only Imix, Kan, or Ben. The most prob-

33.1. Head variant coefficient: (a) with Chen; (b) as coefficient of a Secondary Series; (c) with Kayab; (d) with day sign, probably Imix; (e) head for number 11 from Lintel 2, Piedras Negras.

able reading is Imix, as we have drawn it, although only with dotted lines. The prime importance of the block in Figure 33.1d is the fact that the numeral in which we are most interested is combined with a day, whatever that may be.

I shall now describe the numeral associated with the four calendrical glyphs. In all four cases the face is that of a rather young person (although probably one should not emphasize this detail, as at Palenque the sculptor tends to create pleasing features). On the forehead, in at least two cases, is a tuft of hair with well-defined individual hairs. Starting from the forehead, running over its top and hanging down, at the end of the left cheek to where the left ear should appear, is a ribbon or curl in all four specimens. Finally in examples 1, 2, and 4 the lower jaw is covered by two oval ring-shaped elements. In example 3 the whole face is shown and the two ring elements hang down from the chin.

As stated above, we are dealing here undoubtedly with a head variant of a numeral. Through the association in Figure 33.1d with a day it can not have a value higher than 13 nor can it be 0, as days can be accompanied only by numbers lying between 1

and 13 inclusive. We can also disregard at once the values of 1, 3, 4, 5, 6, 8, 9, and 10 as our head does not possess any one of the well-known characteristics which identify these numerals. There remain then only numbers 2, 7, 11, 12, and 13. Through the findings at Palenque in 1935 it has been proven that the characteristic of number 2 is a head ornament formed by a hand; number 7 is considered to be characterized by a large ornamental scroll under the eye and curling up in front of the forehead; number 13 is a bird's face with a somewhat elaborate hair ornament or the head of 3 combined with the fleshless lower jawbone. Consequently we can eliminate these possibilities, too, leaving for discussion only numbers 11 and 12.

E. J. Palacios (1935:20–21), to whom we owe the definite identification of number 2, discusses and reproduces all known variants of number 12. None of them shows any likeness with our head, and they lack particularly the oval ring-like elements covering the lower portion of the face. The characteristic of number 12 must lie somewhere in a decorative element of the upper portion, and therefore I think we may exclude this numeral also.

Thus by elimination we are forced to identify our newly found four hieroglyphs as head variants for number 11.

Only three examples of head variants for the number 11 are known. One is the katun coefficient of the Initial Series on Stela 6, Yaxchilan. Little can be made out in either Maler's or Morley's photograph. The ring element is not recognizable, but it is possible that a crack runs diagonally across the face, and in that case it is barely possible that part of the ring was chipped off. The second example is also the katun coefficient of an Initial Series. This is on the east altar of Stela 5, Copan. No photograph is available, but Morley's drawing (1920, Pl. 20b) shows no rings on the lower jaw. The head is youthful. What may be

the ribbon or curl visible on the heads under discussion is shown, and it is barely conceivable that the circular element in front of the mouth is the ring.

The third example is again supplied by a katun coefficient, that of Lintel 2, Piedras Negras. I am indebted to Miss Tatiana Proskouriakoff for the drawing, made from the original, shown in Figure 33.1e. The details are not very clear, but it is not improbable that there is a circle on the lower jaw.

The comparative material, unfortunately, does not wholly support the suggested identification. On the other hand, it is not completely irreconcilable. Whether the head form in question does or does not represent the number 11, at least, it is a new variant for some number between 1 and 13 inclusive.

MEXICO CITY

A Possible Lunar Series on the Leyden Plate

Karl-Heinz Nottebohm

Little attention has been paid to 'the glyphs on the Leyden Plate following the record of Glyph G5 and Yaxkin in A7a. It is, however, quite probable that the remaining glyphs form a Lunar Series. Because of the positions of Glyph G5 and Yaxkin, I assume that the four sections comprising each of the two remaining glyph blocks are to be read in the sequence A7a upper, A7a lower, A7b upper, and A7b lower, and then the A8 block in the same order. There are, of course, many precedents for this manner of reading divided glyph blocks. A7b upper and A7b lower are quite similar. The element to the right of Alb lower is the moon symbol, and it is probable that the corresponding element in Alb-upper is the same. I suggest that the rather similar elements to the left of both signs represent hands. In that case the glyphs should represent Glyphs C and D of the Lunar Series, both without coefficients.

The moon age corresponding to the Initial Series, 8.14.3.1.12, 1 Eb 5 Yaxkin, can be calculated from 8.16.0.0.0, the moon age of which is given as 25 days on Stela 18, Uaxactun. The interval is 13288 days, which is 450 moons and 1.2 days, indicating a moon age for 8.14.3.1.12 of 26.2 days. A similar calculation

from 9.4.0.0.0, the moon age of which is recorded as 13 days on Stela 6, Tikal, gives a moon age from the Initial Series of the Leyden Plate of 27.5 days.

The absence of a coefficient with the supposed Glyph C would indicate that a new moon was recorded. Teeple has shown that there may be an error of two or three days in these observations. It is therefore plausible that Glyphs A7b upper and lower state that the Initial Series was that of a new moon, and that that moon was the first of the group.

The lower part of Glyph A8a is the so-called sky sign; the upper part is indistinct. This glyph should correspond to Glyph X of the Lunar Series. It contains elements of Form 6.

Glyph A8b upper displays prominently the bone element which is a feature of Glyph B of the Lunar Series. This glyph should occupy this position immediately after Glyph X. The elbow element, however, is not present. Glyph A8b lower should, if our thesis is correct, be Glyph A of the Lunar Series. It must, however, be admitted that the usual features of that glyph are not discernible. Nevertheless, the material, as a whole, supports the identification of these glyphs as a Lunar Series.

GUATEMALA CITY

Stucco Decoration of Early Guatemala Pottery

A. V. Kidder and Anna O. Shepard

Stucco was used for the embellishment of prehistoric Mexican and Central American pottery in various ways: as a coating, tinted in plain colors, for whole vessels or parts of vessels; as a surface upon which more or less elaborate designs were painted; and as a background of which parts were cut away and filled with colored substances, paint cloisonné. These methods and their distribution have been discussed by Linné (1934) and Ekholm (1942). A fourth process, which has apparently not hitherto been reported, and which, as far as we are aware, involves the earliest known employment of stucco in Mesoamerican pottery decoration, is represented by a small group of sherds from the archaeological site of Kaminaljuyu, near Guatemala City.

The pieces were found in 1938 by Robert E. Smith in the course of stratigraphic excavation on Finca Miraflores in the southwestern part of Kaminaljuyu. They were taken from the lower measures of a thick stratum of rubbish of the Miraflores phase, the oldest so far identified at Kaminaljuyu and believed, on the basis of its handmade clay figurines, to have been roughly contemporaneous with the Middle (Archaic) cultures of the Valley of Mexico and the earliest (Mamom and Chicanel) phases of Uaxactun. As they came to light in a test column whose excavation was personally supervised at all times by Mr. Smith, and as nine fragments were found, there is no possibility such as might be entertained in the case of a single specimen, that they emanated accidentally from a higher, and much later, stratum which at that point overlay the Miraflores deposit.

Four vessels seem to be represented: (A) by a single fragment of a spout (Fig. 35.1a) from Cut 7 (counting from above downward); (B) by a slightly smaller spout (Fig. 35.1b) and five body sherds (two shown in Fig. 35.1c, d), all from Cut 9 and all evidently from the same piece; (C) by two body sherds, perhaps from different vessels (one shown in Fig. 35.1e), from Cut 10, close to the bottom of the test column. All had carried stucco but on only three pieces was it well-preserved.

The vessels were identical in paste and slap composition. Their temper is volcanic ash, in which particles of pumice and clear crystals of feldspar are prominent. They had more or less spherical bodies and, to judge from the roughness of their interiors, small mouths. No orifice fragments, except the spouts, were recovered. The interior surfaces are reddish brown (Pecan Brown of Ridgeway), striated as if by finger-smoothing; the exteriors bear an admirably smoothed, faintly glossy slip, Avellaneous in color in all except imperfectly oxidized sherds, but two of the fragments also have thin and ill-defined areas of Cinnamon. It was not determined whether this brighter color represents a flushing caused in firing or was produced by a wash of different material. No distinct surface film, however, can be detected with a magnification of 50x.

So much for the nature of the vessels as they came from the kiln. The first step in the secondary, or post-firing, treatment was the application of an extremely thin coat of ferruginous clay (c, Fig. 35.2). Although this is visible to the unaided eye on only

35.1. Stuccoed sherds from Finca Miraflores, Kaminaljuyu: (a, b) spouts from Vessels A and B, respectively; (c, d) sherds from Vessel B; areas marked *x*, here and in *e*, have lost all stucco; the area in *d* marked *y* is the unstuccoed lower body, its upper edge slightly below the point of greatest diameter; (e) sherd of Vessel D; Arrows indicate direction of orifice. Colors: Pink represented by horizontal hachure; white by oblique hachure; yellow by cross hachure; green by solid black; dark gray by dots. The grayish background coat of stucco is represented by white, save in areas marked *x* or *y*. Note that in some places parts of design elements have disappeared, exposing the background coat.

one piece, traces can be detected microscopically on the others; also when a flake of stucco is removed a light streaking of red is seen on both the freshly exposed pottery and on the contact surface of the stucco. There was no apparent advantage in the use of this red wash as it is soft and powdery, but it was nevertheless apparently applied only on areas later to be stuccoed: This is indicated by its absence from the unstuccoed area (*y*) of Figure 35.1d, and

suggests that it had some real or fancied utility. Its occurrence on these pieces is of interest because on a certain group of stuccoed vessels from later tombs at Kaminaljuyu (to be described in the report on that site) there is beneath the stucco a similarly colored but thicker undercoat.

The stucco proper of the present specimens is unusual, both in composition and in the nature of its application. Over the thin red wash was spread, in the case of the best-preserved pieces, a coat of grayish white clay, hereafter called the background coat, which served as a base for all subsequent applications and of which parts were left exposed as background for designs, the latter being made up of areas of stucco of various colors.

One would suppose that the simplest and easiest way to produce the same effect would have been to lay on the design elements in stuccoes of appropriate colors. This would have given the desired relief, which could then have been sharpened and emphasized by trimming the edges of the elements. Another method might have been to spread over the grayish white background a continuous secondary coat; to cut parts of this away to re-expose the background and thus achieve a design; and to paint the unexcised areas in the desired colors. Actually, however, each colored area was the result of a separate operation, or rather three operations: first a thick and relatively coarse base-layer (e.g., Fig. 35.2) was applied; this was then covered with pigment (f, h, Fig. 35.2); finally, the edges of the base-layer and of its thin surface layer of pigment were straightened and trued up. Close examination of the edges of the design elements suggests that this was done with a smooth, blunt-pointed implement; and that it was a final step, rather than having been carried out before the thin pigment layer was applied, is indicated by the fact that the latter does not lap over the beveled edge of the base-layer (see sections of edges, Fig. 35.2), as certainly could not have been prevented had it been painted on after the bevel of the base-layer had been produced.

That the above process was repeated in the case of each separate element of the design is proved by various bits of evidence: (1) the base-layers of different elements differ in composition (this will appear in the detailed descriptions which follow); (2) the base-layer of the white band on one of the sherds (Fig. 35.1e) is distinctly thicker than those of the immediately adjacent gray and pink bands (compare left and right sections shown in Fig. 35.2); (3) there are no scratches in the grayish white background coat along the edges of the elements, and such marks could hardly have failed to be made had a continuous coat been cut through.

There follow notes on individual sherds (all bear the thin red primary wash).

A (Fig. 35.1a). Spout. Stucco mostly gone. Only one coat was detected. It is chalky white, thick, and roughly pitted on the surface. It is of diatomaceous earth, composed largely of fragments, but several species are probably well enough represented for identification.

B (Fig. 35.1b–d). Spout and five body sherds. On the largest sherd (Fig. 35.1c) the well-smoothed background coat is of clay, grayish white mottled with darker gray. It is extremely fine-textured and free from mineral grains, but contains a few minute fragments of volcanic glass. Upon ignition it turns white; the gray is therefore undoubtedly due to carbonaceous matter. The pink triangles at the left (slightly deeper in color than Chatenay Pink) have a comparatively thick, deeper pink clay base layer which contains numerous granules of hematite and white clay. In the pink surface pigment there is an abundance of fine volcanic dust (fragments mainly under 0.003 mm in diameter, rarely as large as 0.01 mm) and a few grains of quartz in the same size range. The partially eroded upper rectangle has a base-layer containing sharp grains of clear feldspar, quartz, and hornblende, and fragments of volcanic glass mainly between 0.05 and 0.1 mm in diameter. The surface is pale yellow except at the lower edge, where it blends into a pinkish white, much paler than the pink of the triangles. The base-layer of the lower rectangle is the same as that of the upper, but the surface pigment (badly smudged) is apparently entirely of pale pink clay. The vertical stripe at the left is shown as green in the drawing, although its original color is doubtful. Its form was indicated by an unsmudged area on the background coat. When received in the laboratory this stripe had no base-layer and the only pigment remaining was a small patch of yellow in the upper section blending into orange near the central section. Since the surface of this area is rough and no clear line edges remain, it might be supposed that it represents foreign material deposited on the sherd subsequent to its ornamentation, were it not for the fact that the yellow is identical with the yellow of the upper rectangle, which has a smooth surface and coincides with a design element. All other areas marked green have a thick base-layer of coarse-textured, pale gray-green material; it approaches Pale Olive Buff but is stained. When the surface is scraped it matches Light Mineral Gray. The mineral inclusions are clear feldspar, quartz, hornblende, augite, and opaline fragments. It is coarser-textured than the base-layers

of the pink and yellow rectangles and is comparable to the base layer of the gray and white bands in the better-preserved stucco of Figure 35.1e, although the mineral suite differs. The coarse-grained base-layers have considerable "tooth" because of the sharpness and angularity of the grains, and their texture indicates that they are tempered clays.

The second large B sherd (Fig. 35.1d) is nearly identical in stucco and pigments. It has the usual background coat of mottled grayish clay; the base-layer of the pink design elements contains granules of hematite and white clay; and that of the elements recorded as green is of the coarse-textured, greenish gray material. A few remnants of a fine-textured white clay occur on the surface of the greenish gray material, from which it would appear that the surface pigment of these areas may have been white.

Three of the B sherds retain so little stucco that they are not illustrated. One of them has only remnants of white diatomaceous earth similar to that of Sherd A. A second has a grayish white background coat of the same composition as those of Figure 35.1c, d. It covers three-fourths of the surface, but stops short of what was apparently the rise of the orifice. On the upper edge, overlapping the background coat and extending over the vessel surface, is a chalky white coat containing stray diatomaceous particles. On the background coat is also a yellow substance coarser than the other clays, and similar in color and texture to the yellow of Figure 35.1c. It turns red upon ignition and is therefore probably limonitic. A third fragment of B has a remnant of pink pigment which overlies a granular pink and white base-layer, which in turn is underlain by the usual background coat of grayish white. The pink pigment is the same as that of Figure 35.1c, d.

C. The larger of the two sherds (Fig. 35.1e) has a background coat like that of Figure 35.1c, d. The decoration is of parallel stripes in pink, white, and gray. The pink stripe as usual consists of two layers: a pink and white granular base-layer, and thinner, fine-textured, homogeneous surface pigment which is considerably paler than the pink of the n sherds (paler than bright Vinaceous Fawn). The base-layer of the white stripe is noticeably thicker than that of the pink and gray stripes (see left side of Fig. 35.2). It is a grayish clay containing numerous sharp grains of clear feldspar, green hornblende, brown glass, and flakes of biotite, which are mainly between 0.05 and 0.15 mm in diameter, though a few are as large as 0.5 mm. The hornblende, brown glass, and biotite particles are sufficiently numerous to give this layer a distinctly peppered appearance. The white surface material is a clay containing considerable

35.2. Section at right angles to adjacent edges of gray and white stripes of Figure 35.1e (enlarged about 33 diameters): (a) paste (if whole thickness of sherd were shown at this scale, it would occupy a space of about 20 cm); (b) slip; (c) red wash; (d) background coat; (e) gray clay, tempered base-layer of gray stripe; (f) gray pigment; (g) tempered clay base-layer of white stripe; (h) white pigment. Note different thicknesses and compositions of base-layers of gray (e) and white (g) stripes, which indicate that they were separate applications rather than parts of a single coat from which the intervening area was excised.

volcanic dust. The base-layer of the gray stripe is of tempered clay similar to that of the white stripe; the clay matrix, however, appears somewhat grayer. Its surface pigment (Mouse Gray) is of homogeneous, extremely fine grained clay which ignites to a cream color, and therefore is probably carbonaceous. Above the gray stripe is a remnant of white (see Fig. 35.1e) which is fine-textured and lies directly on the background coat without a tempered base layer. It contains a few diatomaceous fragments. The second C sherd has remnants of a grayish clay background coat and of pink pigment. Also there is a small area of tempered white clay.

To sum up: The varied composition of these stuccoes is no less unusual than the technique of their application. They include clay, diatomaceous earth, clay with an extremely high percentage of volcanic dust, tempered clay, and pigments mixed with clay. The most surprising feature is the absence of calcite, which seems normally to have been employed in stucco work of later times, although clay stuccoes have been found on certain vessels from Esperanza phase tombs at Kaminaljuyu, which will be described in a later report. Another peculiarity of the present specimens is the nature of the

tempered clay base-layers under some of the design elements. These may have served to provide a firm footing for the pigments, functioning like the scratch coat used today in plastering. Formulas for some modern white paints include ground quart, which, being transparent, possesses practically no covering property, but is added to give "tooth" to the paint. The pink elements, with the exception of that of the lower rectangle of Figure 35.1c, have, instead of the tempered base-layer, a nonhomogeneous base, the composition of which suggests an imperfect mixture of hematite and clay.

We have described these specimens in detail because, as has been said, they exhibit the earliest known examples of the decorative use of stucco; also because preliminary study of stuccoed vessels from subsequent horizons at Kaminaljuyu and elsewhere in Mesoamerica indicates that various materials and techniques were employed and that these may prove to have regional and chronological significance. It would be interesting to know if the rather complicated process used to produce colored designs on these Miraflores sherds was a forerunner of the much simpler but equally effective paint cloisonné technique of central and northern Mexico.

Certain Pottery Vessels from Copan

A. V. Kidder

Encroachment of the Copan River upon its right bank a short distance below the Acropolis of Copan resulted in the washing out of human bones and pottery. Following this clue, Mr. Gustav Strömsvik, in 1942, trenched into its bank and discovered a number of graves of different periods, and refuse beds of considerable depth, which yielded valuable stratigraphic data. Shortly thereafter Mr. Strömsvik entered service in the Norwegian Navy and he has therefore been unable to publish the many mortuary vessels or to make studies of the great number of potsherds recovered from the refuse. The cylindrical tripods and basal-flanged bowls illustrated in this Note have been selected for reproduction in advance of a more comprehensive report on Copan ceramics because they are examples of widely distributed types that are proving very useful, in the current research of several investigators, in throwing light on the chronological relationships of, and commercial contacts between, a number of important Mesoamerican cultures.

Cylindrical tripods have long been considered a specialty, so to speak, of Teotihuacan, and wherever found, they have usually been considered to reflect influence, direct or indirect, from that center. But whether or not Teotihuacan actually furnished the inspiration for this form cannot surely be determined until specimens from all Mesoamerican regions where they occur have become available for comparative study. The typology and the distribution of these vessels will be discussed at length in a forthcoming report on Kaminaljuyu by Kidder, Shook, and Jennings.

The basal-flanged polychrome bowl is perhaps even more closely to be associated with an area and a chronological period, namely the Peten-British Honduras region and the early part of the so-called Maya "Old Empire" (the Tzakol phase of Uaxactun and Period II at San Jose). Discoveries of sherds of this type at Teotihuacan by Linné (1942) and of sherds and complete bowls by me at Kaminaljuyu indicate approximate contemporaneity of Periods II or III of Teotihuacan and the Esperanza phase of Kaminaljuyu with the above-mentioned Uaxactun and San Jose phases. But the full significance of such finds will become evident only when we have fuller information as to the subtypes of basal-flanged bowls, their distribution, and the exact periods to which they belong. Present knowledge regarding basal-flanged bowls is summarized and their archaeological importance is made clear by Thompson (1939).

Eventually the cylindrical tripods and the basal-flanged bowls from Copan can probably be assigned to a definite period in the life of that city and one which can in all likelihood be approximately dated in terms of the Maya calendar. This, however, will not be possible until the ceramic, stratigraphic, and epigraphic data gathered by Mr. Strömsvik and Dr. Longyear have been correlated. In the meantime, it is possible only to state that Dr. Longyear (personal information) believes both types, as represented at Copan, to pertain to the earlier part of the Old Empire. This reinforces conclusions based on the evidence from other sites.

The paintings are by Antonio Tejeda P.

36.1. Pottery vessels from Copan.

Fig. 36.1a. Basal-flanged polychrome bowl, black and red on orange. The very wide flange, the decoration of the inner side of the rim, and the red U-shaped elements on the exterior ally this bowl very closely with specimens from Esperanza tombs at Kaminaljuyu (Thompson 1940b, Pl. IV, a).

Fig. 36.1b. Cylindrical tripod, polished black; carved decoration, the excised parts filled with cinnabar. The carving is deeper than in the so-called "champlevé" technique of Teotihuacan tripods (cf. Linné 1934, frontispiece).

Fig. 36.1c. Basal-flanged bowl with lip spout, black and red on cream underslip, unclipped below flange. In shape (i.e. relatively short flange springing abruptly from a rather straight upper wall), in possession of lip spout, and in use of triangles as flange decoration this piece resembles bowls from Uaxactun (cf. R. E. Smith, 1936, Fig. 6, no. 1). Save for the spout, it has like analogies with a specimen from Kaminaljuyu (cf. Fig. 72 in the forthcoming report on that site).

Fig. 36.1d. Cylindrical tripod with cover, in light brown slip leaving incised panels "reserved" in cream underslip. In shape of both body and cover and in possession of light-colored panels bearing glyph like designs, this vessel much resembles a tripod from Kaminaljuyu, but the latter is black and its decoration is on stucco, the "reserved" white panels being set off by a red background (cf. forthcoming report, Fig. 204c).

Fig. 36.1e. Cylindrical tripod, polished black, incised decoration rubbed with red (cinnabar?) paint. Large panels containing double hook-shaped elements like these and those of g, occur on cylindrical tripods from Uaxactun (information from R. E. Smith).

Fig. 36.1f. Cylindrical tripod, gray, lighter gray serpent produced by negative painting. Tripods decorated by negative painting have been 'reported from Teotihuacan (Linné 1934, Fig. 23) and Uaxactun (R. E. Smith 1936, Fig. 8, no. 5).

Fig. 36.1g. Cylindrical tripod, pinkish gray, incised decoration.

Archaeological Specimens from Guatemala

Robert E. Smith

The pottery and other artifacts herein illustrated are contained in various private collections. Precise data as to the circumstances under which most of them were discovered are lacking, but the proveniences assigned them by their owners are probably correct. They should therefore be useful for distributional studies. Furthermore, representatives of pottery or other artifact types now recognized, or which may be recognized in the future, have value in adding to the corpus of information regarding those types; and in the case of categories of pottery that are known to archaeologists only in the form of sherds, whole pieces such as these are desirable for the light they can shed on vessel shapes and systems of decoration. Finally, it is always well to make a record of material in private hands, for not only is it often difficult of access to students, but there is danger that it may become scattered and lost to science.

Paintings and drawings are by Antonio Tejeda F. In the descriptions, Ridgway (1912) color readings are capitalized. Scale of illustrations: Fig. 37.1, $\frac{1}{4}$, except h, which is $\frac{1}{8}$; Fig. 37.2, $\frac{1}{4}$; Fig. 37.3, $\frac{1}{3}$; in Fig. 37.4 the longest celt measures 11.5 cm; b-d, $\frac{1}{2}$.

SPECIMENS FROM DEPARTMENT OF SAN MARCOS

Eleven pottery vessels, two potsherds, two effigy whistles, and a number of objects of jadeite and other green stones, the property of Mr. Hyde T. Clayton. The lot is said to have been found together in a mound at San Miguel Ixtahuacan. The objects of

stone and a small bit of sheet copper are reported to have been contained in the two vessels illustrated in Figure 36.1b, d.

Fig. 37.1a. Small jar with circular flattened areas on four sides; slip brown to black, paste Hazel; badly weathered.

Fig. 37.1b. Tripod vessel; incised decoration; heavy weathering renders presence or absence of slip uncertain; paste Ferruginous (cf. Gamio 1926-1927: 210, upper left).

Fig. 37.1c. Jar; pre-slip incised decoration; brownish, badly weathered slip covers whole exterior, and interior of rim.

Fig. 37.1d. Tripod vessel; post-slip, but probably pre-firing, incised decoration into which red paint has been rubbed; slip brownish (cf. Gamio 1926-1927: 210, upper right).

Fig. 37.1e. Jar; pre-slip incised decoration; brown to black slip covers whole exterior, and interior of rim; apparently well polished.

Fig. 37.1f. Tripod vessel, too severely weathered for determination of color of slip, if any; paste Cinnamon Rufous.

Fig. 37.1g. Tripod bowl; incised decoration applied before polishing, when clay leather-hard; apparently unslipped; color dark brown.

37.1. Pottery vessels from Guatemala.

Fig. 37.1h. Large jar; paste near Vinaceous Rufous, slip? Thumb-punched fillet on neck and pairs of pre-slip (?) grooves on opposite sides of body (reproduction at 1/8).

Fig. 37.1i, k. Pot stands. i. Interior Cinnamon Rufous; there was perhaps primary slip on the exterior, which way covered by an Ocher Red slip with specular hematite inclusions; k. Paste Ferruginous, slip badly weathered; one side heavily burned, apparently subsequent to original firing. Pot stands have been reported from Tzimin Kax, British Honduras (Thompson 1931, Pls. XL, XLII); in Guatemala from Holmul (Merwin and Vaillant 1932, Pl. 19e, g) and

Zacualpa (Lothrop 1936, Fig. 38); in Mexico from Monte Alban (Caso 1938, Figs. 36–38), Cerro de las Mesas (Drucker 1943a, Pl. 21a, b), and the west coast (Kelly 1944).

Fig. 37.1j. Tetrapod (?) bowl, fragmentary; feet contain rattles; paste Hazel; slip Ferruginous to Cinnamon Rufous, interior somewhat cracked.

Fig. 37.1l. Tripod bowl, pre-slip incised decoration; brownish black slip on interior, exterior Cinnamon Rufous.

Fig. 37.3d. Whistles; brownish black; the pre-slip (?) incised and gouged decorations below the monkey face are filled with red paint.

Fig. 37.3f. Fish effigy vessel; pre-slip incised decoration; paste Chestnut Brown, slip brownish to deep black, originally well polished. Fish effigies, not clearly similar to the present example, have been found at Santa Rita, British Honduras (Gann 1900, Pl. XXXV; see also Joyce 1927:105), and at Kaminaljuyu in a tomb of the Esperanza phase (Maya Research 3:183).

Fig. 37.4a. Jadeite and green stone objects. Top row. 38 beads, subhemispherical; biconically perforated; all are light green and some are apparently of jadeite; diameters 0.4–2.8 cm. At right 3 pairs of jadeite earplugs; diameters 1.7–4.0 cm; some bear traces of red (cinnabar?) paint. Middle row: 149 cylindrical beads, gray to green, some with micaceous inclusions; mostly biconically perforated, but a few have a straight bore of uniform diameter. Lengths 0.9–4.1 cm. Bottom row: 3 green stone celts, lengths 6.0–11.5 cm. At right 27 unperforated cylindrical objects varying from gray to light green, many with micaceous inclusions. Lengths 1.6–10.6 cm. These specimens, because of their size and shape and because of the nature of their material, would seem to have been tubular beads awaiting perforation.

Remarks. The pottery from Ixtahuacan gives a definite impression of earliness, because of the resemblance of some of the vessels, in shape and in the nature of their incising, to specimens from the Salcaja-Momostenango region believed by Gamio (1926) and Lothrop (1926) to be early. Small, solid, conical feet are, in general, an early feature, as is the grooved lip of Figure 36.11. The swollen, probably tetrapod, feet of the latter bowl are of the sort appearing at Holmul in Period I (Merwin and Vailant 1932, Pl. 18), at Tzimin Kax on what Thompson (1931:285, Pl. XL) considers a Holmul I horizon, at Santa Rita and Nohmul, British Honduras (Gann 1918, Pl. 13b; Gann and Gann 1939:50), at Monte Alban in Period II (Caso 1938, Fig. 42), and at Copan in Usulután ware of the pre-acropolis period (information from J. M. Longyear). The filling of incised decoration with red paint was commonly practiced during the Miraflores phase the earliest as yet identified at Kaminaljuyu.

In view of the above and of the absence of any piece of known late type, I am inclined to doubt that the scrap of copper was found in association with these vessels. If such was actually the case, they would have to be assigned to a relatively recent period.

SPECIMENS FROM THE COBAN DISTRICT, ALTA VERAPAZ

Fig. 37.4b. Large, hollow, moldmade figurine; unslipped, slightly lighter than Mouse Gray; two sus-

pension (?) holes through headdress; part of a circular vent remains behind right ear (see section). Although its back is missing, this object was certainly a whistle (cf. the figurine whistles, also from Verapaz, illustrated by Dieseldorff 1926, Pl. 8, one of which is almost a duplicate of the present specimen). Found on a high hill on Mrs. R. W. Hempstead's Finca Chicoyou, in the northwest outskirts of Coban.

Fig. 37.3c. Tripod plumbate jar; typical plumbate gray, slightly darker than Dark Olive Gray, vertical part of body and lower body browner; surface shows considerable popping.

Fig. 37.3e. Small plumbate effigy jar; typical plumbate gray (Ridgway reading not made). Both this and the foregoing vessel acquired in Coban, no further data. Although a number of similar pieces have been figured, it seems well, in view of the great interest which attaches to this ware, to provide material showing even minor variations of shape or decoration.

Fig. 37.4c. Fragment of similar moldmade figurine, also doubtless a whistle. Paste Ferruginous, slip Pecan Broom. Found by me in excavating a refuse bed discovered during road work on Miss Rosita Dieseldorff's Finca Chipoc, adjoining Finca Chicoyou.

Fig. 36.4l. Hollow Jaguar (?) head with rattle; evidently broken from a vessel, part of whose apparently upper wall remains at the back; circular vent in top of head. Acquired in Coban, no further data.

VESSEL FROM DEPARTMENT OF SUCHITEPEQUEZ

Fig. 37.3g. Cylindrical vase; incised, painted, and appliquéd decoration; slip Kaiser Brown; lip and wall above topmost incised line painted red; post-drying, but pre-slip, incising; tau-shaped elements, animals, and interpanel areas painted brown; negative-painted circles with central dot in two interpanel areas; on one side an appliquéd monkey head. Acquired in Coban, said to be from Ingenio Palo Gordo.

VESSELS FROM LAKE PETEN ITZA

These five specimens, the property of Sr. Federico Gonzalez, are reported to have been found at San Jose on the north shore of Lake Peten Itza, Department of the Peten.

37.2. Pottery vessels from Guatemala.

37.3. Pottery vessels from Guatemala.

a

b

c

d

37.4. Pottery vessels from Guatemala.

Fig. 37.2f. Incense burner; pedestal base broken off; orifice slightly oval lengthwise (13 by 12.2 cm); a circular hole below each earplug and one in center of floor; surface unslipped, gray to Salmon Color; interior heavily burned. This is undoubtedly a relatively modern Lacandon incense burner, almost identical specimens having been observed in use by these Indians and others having been found, evidently recently deposited, at various ancient sites: Chiapas and Tabasco (Seler 1908:585–89); Yaxchilan, Lago de Petha, Palenque, Piedras Negras (Tozzer 1907, Fig. 26, Pls. XVII, XIX; Butler 1935, Pl. 6(18); Quintana Roo (Gann 1918, Fig. 69; 1927:56).

Fig. 37.2e. Cylindrical tripod; gashed solid slab feet; incised decoration; black slip covers entire vessel save exterior base and feet. Although the cylindrical tripod has a wide distribution on the Tzakol–Teotihuacan III–Esperanza horizon, specimens with the present type of gashed foot have hitherto been found only at Kaminaljuyu (information from A. V. Kidder) and San Agustín Acasaguastlan, Late phase (Smith and Kidder 1943, Figs. 25, e, f; 26; 38q, r) in Guatemala, and at Copan in Honduras (Peabody Museum, Harvard University).

Fig. 37.2h. Cylindrical vessel, pre-polish incised decoration (the small circles are hand-incised, rather than punched with a reed-end while the clay was still soft; cf. Smith and Kidder 1943, Fig. 47d, a vessel from San Agustín Acasaguastlan; cf. also Fig. 44d, a cylinder from the same site, with stepped frets resembling those of the present specimen); slightly indented ring in base (this feature also occurs at San Agustín Acasaguastlan, Magdalena phase: Smith and Kidder 1943, Figs. 24b, 43b); surface, originally well polished, badly weathered, grayish brown, possibly unslipped.

Fig. 37.3a. Bowl with restricted orifice, post-slip incised decoration; well-polished black slip from 1–5 cm within orifice to slightly below point of greatest diameter, rest of surface cursorily stone-smoothed. In distribution of polish this piece resembles an incised bowl of somewhat similar shape from San Agustín Acasaguastlan, Late (?) phase (Smith and Kidder 1943, Fig. 49b).

Fig. 37.3b. Cylindrical vessel, grayish brown slip, severely weathered and stained, over whole exterior and down 2 cm on interior. The relatively short cylinder is a characteristic shape at San Agustín Acasaguastlan in the Magdalena phase (Smith and Kidder 1943, Fig. 25a–d, h).

Remarks. The resemblance of the above five vessels to specimens of both the Late and Magdalena phases at San Agustín Acasaguastlan suggests that cultural connections between the Lake Petén Itza and Middle Motagua regions may have existed over a considerable period of time.

CEREMONIAL WARE FROM DEPARTMENT OF THE PETEN

These five objects (Fig. 37.2a–e), the property of Sr. Emilio Cordon, are said to have been found at Paso Caballo, northwest of Lake Petén Itza. All save e, which is Wood Brown, are of brick-red clay. Although they are much weathered, a thin slip can apparently be made out on their carelessly smoothed and somewhat popped surfaces. Four show faint traces of red and blue paint of the impermanent sort often seen on incense burners.

That these objects played a ceremonial role there can be no doubt, as in ware, crude appliqué modeling of the faces, supplementary decoration with appliqué fillets and “buttons,” and possession of vertical flanges, they are obviously allied to the flanged incense burners so commonly found in many parts of Middle America (see, for example, the specimens from Chacula figured in Seler 1901). But their open bases render them unfit to hold a charge of incense. They might have served either as removable chimneys for burners or possibly, like pot stands, to support an incense receptacle.

The only specimens of the same nature as these that I know of were found in a ceremonial cache at Uaxactun. Although squattier, they also have open bases and bear crudely modeled faces flanked by vertical flanges (Ricketson and Ricketson 1937, Fig. 191, Pl. 85e–g).

Jottings on Inscriptions at Copan

J. Eric S. Thompson

The purposes of this paper are to propose alternative readings of some dates at Copan, and to suggest that for a short while at Copan lunar data were recorded in some system which increased the recorded moon ages of dates by two or three days from what might have been expected.

At 9.11.0.0.0 12 Ahau 8 Ceh the priest-astronomers of Copan were extremely active, to fudge by the number of stelae erected there at that time. No less than seven monuments (Stelae 2, 3, 10, 12, 13, 19, and 23) commemorate that katun-ending or record dates immediately anterior thereto. Certain stylistic peculiarities make it virtually certain that all seven monuments were erected within a few years of one another. The decipherment of the Initial Series on several of them presents serious difficulties.

A quarter of a century has passed since Morley tackled these involved texts. In that interval progress in the field of Maya epigraphy has provided various aids and arithmetical checks to decipherments not then available. Nevertheless, several of Morley's readings, expertly made without these aids, are undoubtedly correct. His decipherments of the Initial Series of Stelae 10, 19, and 13 as respectively 9;10.19.13.0 3 Ahau 8 Yaxkin, 8.10.19.15.0 4 Ahau 8 Chen, and 9.11.0.0.0 12 Ahau 8 Ceh have been amply confirmed by data since brought to light. Similarly there can be no challenge to his readings of the date 9.11.0.0.0 12 Ahau 8 Ceh recorded as a Period Ending on Stelae 2, 12, and 23. Some obscurities that baffled him still remain.

The Initial Series of Steles 23 was correctly read by Teeple as 9.10.19.12.8 8 Lamat 1 Yaxkin. This decipherment

has been confirmed by the form of the Initial Series introductory glyph.

The Initial Series on the east side of Steles 3 was read by Morley as 9.11.0.0.0 12 Ahau 8 Ceh. However, Beyer's subsequent study on the Initial Series introductory glyph invalidates this reading. The central element of that glyph is nest the so-called new fire symbol required by Ceh, but a youthful face, such as serves as the head of the patron of the month Kayab (Fig. 38.1a). Furthermore, the Lunar Series fails to agree with a reading of the Initial Series as 9.11.0.0.0 12 Ahau 8 Ceh.

The cycle and katun coefficients are missing. The tun coefficient is a youthful face with what are almost certainly dots around a very clear jawbone. Accordingly, the best reading of the head is 19. The uinal coefficient is gone; that of the kin has a hand clasping the lower jaw, the symbol for zero. There follows a Lunar Series which reads 10 ?D (the jawbone and the circle before the forehead are very clear), 3C, tasseled variant of Glyph X, Glyph B, 10 A.

The next glyph is 12 Ahau, but the month sign which should follow is suppressed. Instead there are carved two outstretched hands, a glyph of unknown meaning, 13 uinals, the two outstretched hands repeated, 8 Ceh, 11 katuns.

The best interpretation of these data is:

I.S.	9.10.19.5.0	12 Ahau (13 kayab)	
S.S.	13.0	add	
P.E.	9.11.0.0.0	12 Ahau 8 Ceh	11 katuns

The concluding glyphs form an abbreviated equation, 12 Ahau serving for both dates. As we shall see, the moon age, if correctly interpreted as 10D, is in agreement with the proposed reading of the Initial Series.

The Initial Series on the west or inclusion side of Stele 3 (Fig. 38.1b) was read by Morley as 9.4.0.0.0 8 Ahau 13 Ceh. This decipherment must also be disallowed, and for the same reason that led to the rejection of the Initial Series on the east side. The central element of the initial Series introductory glyph is a somewhat reptilian head, not the new fire symbol of Ceh.

The cycle coefficient is 9. The head which forms the coefficient of the katun is partly gone, but the jawbone is clear. The katun coefficient must, therefore, be 10 or more, but as it is extremely unlikely that the Initial Series is later than the date of the monuments erection (9.11.0.0.0 12 Ahau 8 Ceh), the katun coefficient is almost surely 10. Morley reads this as zero, having noted a clear case of the use of a head with jawbone for zero on Stela 19 of this group. The example cited, however, is extremely irregular, and might well be the result of careless copying of a hand in the original drawing by the sculptor who executed the design. It should hardly be used as a precedent for interpreting other heads with jawbones as zero.

The head which serves as the tun coefficient has a prominent jawbone with a circle above it, indicating that it represents the number 19. As added confirmation of this identification, it will be noted that the forehead ornament is similar to that of the head for 9 which serves as the cycle coefficient.

Little remains of the uinal coefficient. The head which denotes the number of kips has a circle around the eye. The ramus of a jawbone is clearly visible. The value, therefore, must be 10 or more. The next glyph block, which once held the day sign, is entirely gone. Next is what is presumably Glyph G of the Lunar Series. The interior is crosshatched. The superfix may be that of Glyph F, suggesting that, as is often the case, the two glyphs are combined.

There follow Glyphs E and D, combined in, one quarter glyph block, and with no coefficient. Glyph C is obliterated, but the form of Glyph X, the tasseled variant, indicates that the coefficient of Glyph C must have been 2 or 3. There follow Glyphs B and A, the latter with a coefficient of 10. Morley, who made his drawing of this Lunar Series at a time when its function was unknown, arranges the four glyphs of this glyph block in the order top left, top right, bottom left, bottom right, whereas it is amply clear that in this inscription they should be read top left, bottom left, top right, bottom right. As a result

of this error, he is forced to read Glyphs D and E as Glyph C. This he does by converting Glyph E into a hand, and making it part of Glyph C.

Following a glyph of unknown meaning, but with a coefficient of 9, there is recorded the month position 4 Cumhu. The superfix is somewhat unusual, but occurs with an undoubted Cumhu on Stela 23, one of the monuments under discussion. The main part of the glyph and its coefficient of 4 are quite clear. Money appears not to have recognized this 4 Cumhu, which, of course, would be meaningless were the Initial Series in truth 9.0.0.0.0 8 Ahau 13 Ceh.

In view of the month position 4 Cumhu, the day sign must be Imix, Cimi, Chuen, or Cib. As the kin coefficient is over 10 but is certainly not 16, all these day signs except Chuen can be eliminated. Accordingly the coefficient must be 11. It is true that the hand does not resemble known forms of the head for 11, but these are very few in number. Also, as there are two head forms for 13, one of which combines elements of the heads for 10 and 3, it is probable that 11 could also be written combining elements of 10 and 1.

The only possibilities are:

9.10.11.3.11	2 Chuen 4 Cumhu
9.10.15.4.11	6 Chuen 4 Cumhu
9.10.19.5.11	10 Chuen 4 Cumhu

Of these the second can be eliminated because the tun coefficient certainly is not 15, and because the lunar data are in disagreement. The first can be eliminated because the recorded moon age also fails to agree with this reading. There remains only the third date. This, as we shall see, is in agreement with the moon age, recorded as 20 days. It also agrees with the preferred reading of the tun coefficient.

The Initial Series, therefore, must be 9.10.19.5.0 12 Ahau 13 Kayab on the east side, 9.10.19.5.13 10 Chuen 4 Cumhu on the west side.

The Initial Series of Stela 12 presents many difficulties. Morley was sure only that the katun coefficient was 10, that the day was 6 Ahau and that the month had a coefficient of 13. To Morley's criteria we can add that the Lunar Series opens with Glyph G8, and that the moon age is 3D. On the other hand, it is not certain that the day sign is Ahau, and conceivably the month coefficient might be 11 or 12. This last is extremely unlikely.

Morley's reading, 9.10.15.0.0 6 Ahau 13 Mac, disagrees with the recorded form of Glyph G. Beyer's reading of the date as 9.30.2.13.0 6 Ahau 13 Zac yields a moon age of around 16D, and for that reason must also be rejected.

38.1. Inscription on Stela 3, Copan: (a) east side, top and bottom; (b) west (inclusion) side, top, and bottom.

If we assume that the month coefficient is 13, the day sign must be Chicchan, Oc, Men, or Ahau. Only readiness at intervals of 585 days will bring the day sign, its coefficient, and the required form of Glyph G into agreement. This is because 585 is the lowest common multiple of 5, 13, and 9, the intervals at which the three factors repeat themselves. There are 12 dates in Katun 10 which meet these conditions. The series starts with 9.10.1.1.15 6 Men 18 Cumhu and ends with 9.10.18.17.10 6 Oc 3 Ceh, but of these only three have month coefficients of 13. These are:

no. 2	9.10.2.13.0	6 Ahau 13 Zac
no. 8	9.10.12.8.10	6 Oc 13 Zotz
no. 9	9.10.14.1.15	6 Men 13 Muan

Nos. 2 and 8 can be eliminated because the calculated moon age at those dates fails to agree with the recorded 3D. There remains only No. 9, 9.10.11.1.15 6 Men 13 Muan.

A re-examination of the Initial Series reveals that the head which serves as the tun coefficient is shown in Morley's drawing with a loop beneath a round eye, indicating that it is the head for 4, 14, 7, or 17. This detail is not clear in available photographs.

Photographs show, however, that the headdress of the head of the kin coefficient bears a fair resemblance to the tun sign which forms the headdress of the heads for 5 and 15. As a jawbone is distinctly visible, the head can not be that of 5 but might well be that of 15. The uinal coefficient, with its strange headdress, resembles no known head variant for the number 1, but a sweeping line visible beneath the earplug may well be the end of the lock of hair which is a prominent and constant characteristic of the head for 1.

Finally, let us examine the day sign. Examples of Men on monuments of the Initial Series period are not numerous. The best preserved are on Lintel 3, Piedras Negras; Stelae 23 and 29, Naranjo; and Stela 17, Tikal (twice). The characteristics appear to be a hooked nose, a square or round eye, a cap, and a lateral perpendicular ornament in the vicinity of the ear. These features are to be seen with varying clarity on all the examples cited, the best delineation being that on Lintel 3, Piedras Negras, which is as clear now as the day it was sculptured. In the codices the head is treated cursively, but there is usually a line across the top of the head, presumably corresponding to the line where cap and forehead meet on sculptured examples. In the bottom right corner there are usually three hooks or slightly curving lines, which might well correspond to the base of the lateral ornament of the sculptured glyphs. I find no evidence

that the serrated teeth are, as is generally supposed, a constant characteristic of the head for Men.

The day sign on Stela 12, Copan, is somewhat weathered. There is a smallish rounded eye, a very clear cap, a nose that has no marked features so far as one can make out, a curved lateral ornament in the vicinity of the ear, and some curved lines at the bottom right corner. With a little imagination (I use the word advisedly) one can reconstruct the weathered profile to produce a Hebraic nose reaching almost to the cartouche edge at the bottom. Although these characteristics are not in very close accord with those listed above, they are by no means at variance. The head is not necessarily that of Men, but there is no reason why it should not be so considered.

On the off chance that the month coefficient might be 11 or 12, I prepared lists of dates at intervals of 585 days, and applied the same tests to them. Not one is satisfactory.

The Initial Series may accordingly be accepted with a slight reservation as 9.10.14.1.15 6 Men 13 Muan.

The Initial Series of Stela 2 must be omitted from the discussion. The inscription is so incomplete and weathered that it is impossible to submit it to the tests already employed. If, as is highly probable, the glyph following the day sign is

Glyph G of the Lunar Series, Morley's reading of 9.10.15.0.0 6 Ahau 13 Mac must be incorrect. Furthermore, it is very doubtful that the day sign is Ahau, and less likely that the kin coefficient is zero.

The moon age of 9.11.0.0.0 12 Ahau 8 Ceh is given very clearly on Stela 13 as 5D. The same moon age of 5D will be reached for 9.11.0.0.0 if all multiples of moons (29.5306) are removed from the intervals between three of the Initial Series in this group of seven stelae and 9.11.0.4.0, and if the remainder in each case, is added to the recorded moon age. That, however, is not the case if the process is repeated for other stelae at Copan. In other cases calculations lead to a moon age of 1-4D for 9.11.4.0.0, usually 1D or 2D.

These results are presented in Table 38.1. The calculated moon age of 9.11.0.0.0 is given to the nearest day. 'Exact' means a deviation of not over one-tenth of a day. The readings suggested above have been included, as well as that of 9.13.18.17.9 of the Hieroglyphic Stairway, the moon age of which is clearly 27 (note the loop under the eye and over the nose). I have omitted dates, such as 9.7.5.0.8, which were calculated far into the past; one or two listed by Teeple which are quite doubtful; and that of Stela M, since the coefficient of 5 is open to doubt. I have also omitted that of Stela 9 which appears to have an error in the moon age, since 5D is recorded where one would expect about 27D. Dates from the 9.11.0.0.0 group are boxed so that they may be more readily recognized.

Table 38.1. Moon Ages for Copan.

<i>Monument</i>	<i>Initial Series</i>	<i>Moon Age</i>	<i>Distance to 9.11.0.0.0</i>	<i>Calculated Moon Age of 9.11.0.0.0</i>
Stela 7	9.9.0.0.0	13D	14400 days (487 moons, 18.6 days)	2D exact
Stela P	9.9.10.0.0	9	10800 days (365 moons, 21.3 days)	1 minus
H.S. 5	9.9.14.17.5	23	9015 days (305 moons, 8.2 days)	2 minus
Stela 12	9.10.14.11.5 ?	3	2125 days (71 moons, 28.3 days)	2 minus
Stela 23	9.10.18.12.8	5	472 days (15 moons, 29 days)	5 minus
Stela 3	9.10.19.5.0	10	260 days 8 moons, 23.8 days	4 plus
Stela 3	9.10.19.5.11?	20	249 days (8 moons, 12.8 days)	3 plus
Stela 10	9.10.19.13.0	23	100 days (3 moons, 11.4 days)	5 minus
Stela 19	9.10.19.15.0	4	60 days (2 moons, 1 day)	5 exact
Stela 13	9.11.0.0.0	5	0 days (0 moons, 0 days)	5 exact
Altar 5	9.11.15.0.0	28	5400 days (182 moons, 25.4 days)	3 minus
Stela 1	9.11.15.14.0	12	5680 days (192 moons, 10.2 days)	2 minus
Stela I	9.12.3.14.0	0	8560 days (289 moons, 25.7 days)	4 minus
Altar H'	9.12. 8. 3. 9	22	10149 days (343 moons, 20 days)	2 exact
Stela 6	9.12.10.0.0	22	10800 days (365 moons, 21.3 days)	1 minus
Stela J	9.13.10.0.0	18	18000 days (609 moons, 15.9 days)	2 plus
H.S. 10	9.13.18.17.9	27	21229 days (718 moons, 26 days)	1 exact
Stela A	9.14.19.8.0	15	28600 days (968 moons, 14.4 days)	1 minus
Stela D	9.15.5.0.0	8?	30600 days (1036 moons, 6.3 days)	2 minus
Stela N	9.16.10.0.0	1	39600 days (1340 moons, 29 days)	2 minus

The table makes clear that Copan during most of its history would have calculated the moon age of 9.11.0.0.0 as 1-3D. Yet on five stelae of the group erected at 9.11.0.0.0 the moon age of that katun was accepted as 3-5D. On one stela of the group, Stela 12, the lunar data lead to a moon age of 2D for 9.11.0.0.0. However, the decipherment of the Initial Series is not absolutely certain. On stylistic grounds Spinden considers this stela to be the earliest of the group, a finding with which the proposed reading agrees. It is therefore possible that this stela was erected before the shift in moon age was authorized.

As three of these stelae reach a moon age of 5D for 9.11.0.0.0, this deviation from normal can hardly be an error. Furthermore, as observation and calculation would show that the reckonings were out of kilter, one must assume that the difference was deliberate. Either the moon age of the point from which the reckoning was made was shifted or a new lunar formula was employed.

Purely as a hypothesis one might suggest the following explanation. Teeple has produced some evidence that Copan at 9.12.10.0.0 used the formula 149 moons equal 12.4.0, and thereby reached a moon age of 22D for 13.0.0.0.0 4 Ahau 8 Cumhu. He has also shown that by the Palenque formula a moon age of

24D was obtained for the same date. A combination of the Palenque 24D base (perhaps firmly established by tradition) and the 149-moon formula would produce a moon age of 4-5D for 9.11.0.0.0. Alternatively, the point from which the moon age was counted might have been shifted from the appearance of the new crescent to the disappearance, some three days earlier of the crescent of the waning moon.

The former hypothesis seems more probable, because the date 13.0.0.0.0 4 Ahau 8 Cumhu is recorded on Stele 23. It is linked with a repetition of 8 Lamat 1 Yaxkin, which, in turn, is followed by a hand ending sign and a glyph which appears to combine the Cauac glyph with a moon sign, as though to indicate that the two dates were linked by a solar-lunar formula. Nevertheless, the interval is not an integral number of moons by any known Maya formula.

At 9.11.0.0.0 the Maya knew that the correction in their calendar amounted to (two solar years and) half a tun. The Gregorian correction would have been two solar years and 182-3/4 days, but Maya corrections generally ran about two days under Gregorian at that date. This correction is probably indicated on Stele 19, the Initial Series of which, as pointed out by Teeple, is a determinant of 8 Cumhu (8 Chen + 180 =

8 Cumhu). This suggests that in some way a lunar-solar formula was under consideration at that time.

Whatever the solution of this divergence may be, Copan, repenting of its heresy, soon returned to orthodox dating of the moon age, and not much later adopted the uniform system of lunar reckoning.

One other matter which may be of consequence emerges from the tabular presentation of calculated moon ages. The date outside the 9.11.0.0.0 group of stelae which has the highest moon age in terms of 9.11.0.0.0 is one which, according to Teeple's interpretation, records new moon because there are no lunar coefficients. The glyphs are of rather unusual types, and it is therefore possible that they do not record new moon, but the last day of the old moon. Thereby the calculated moon age of 9.11.0.0.0 for that date would be reduced by one day, bringing it into closer conformity with the others. Teeple considers that when both Glyphs E and D are present without coefficients, they record new moon. Such an interpretation is highly illogical. They should denote 20, and that is how I have translated the Lunar Series on Stela 3 (west). Teeple's thesis arose from inability to distinguish certain extraneous glyphs, meaning 'day' from Glyph E. At first glance the weathered Lunar Series on Stela 13, Piedras Negras, might appear to support the Teeple thesis. However, the glyph identified by Teeple and Morley as E might equally well be D since it is impossible to see whether the central element is a circle or an oval, the latter being indicative of Glyph D as established by Beyer. Glyphs D and E are both without coefficients on Stela 4, Piedras Negras, the Initial Series of which calls for a moon age of around 20 days. Indeed, Teeple reads the combination as 20, thereby contradicting his own thesis.

Altar L, Copan, has an abbreviated inscription, the first two glyphs of which Morley reads as 2 Chicchan 3 Zip and places at 9.16.1.0.5. He identifies the month sign as Zip on the strength of the somewhat unusual suffix. This, he notes, occurs twice at Copan with indubitable examples of Zip. However, this same suffix also occurs with Uo. Among several examples might be cited those on Lintel 31, Yaxchilan; Altar 1, Hatzcab Ceel; and Stelae 12 and 23, Naranjo. It can not, therefore, be used in differentiating between Uo and Zip. On the other hand, this month glyph on Altar L has a very clear crosshatched area at the top. This, the symbol for black, is precisely the identifying characteristic of Uo. This it shares with Chen. Gates has shown that the word 'black' enters into the name for this month in the calendar from the Alta Verapaz. The characteristic of Zip, on the other hand, is the symbol for red.

As the month here sculptured is undoubtedly Uo, there remains only the question of placing the Calendar Round date in the Long Count, for Morley's identification of the day sign as Chicchan can be accepted. In view of the general style, the position 9.17.11.4.5 2 Chicchan 3 Uo can be used with little hesitation.

For the dubious date reached by a long-distance number on Stela N, Copan, Beyer (1932) has proposed 15.7.15.14.0.0 1 Ahau 8 Chen, over 100,000 years into the future. This he does by changing the tun coefficient of the distance number from 10 to 4. However, the distance number is followed by a variant but recognizable form of the anterior date indicator. The distance number, therefore, must be subtracted, not added. In fact, most long-distance numbers are into the past, not the future. There is another objection to Beyer's reading. Goodman, Bowditch, Morley, and Beyer accept the month sign as Chen, but there are no valid grounds for this identification. The knotted element can occur with Yax (Lintel 21, Yaxchilan), Zac (Stela 1, Piedras Negras), and Ceh (Temple of Sun, Palenque), as well as with Chen. This is not a symbol whereby Chen can be distinguished from the other month signs of the Cauac group but an element which all may take, and which, therefore, pertains to the Cauac element, not to the prefix. It is sometimes the only prefix of Chen because the usual prefix of that month, the symbol for black, may appear as an infix instead of a prefix.

On the glyph in question the symbol for black (a prefix with crosshatching or an infix also crosshatched) is completely wanting. Instead, we find the knotted element as superfix and a strange prefix to the left. This last is shown by Maudslay as a thumb. However, a thumb is never employed as a prefix for a month. Clearly there is an error, either in Maudslay's drawing or in the original. Yet a slight change will convert the thumb into the prefix of Zac. An unpublished photograph in Peabody Museum, Harvard University, shows that the curve to the left of Maudslay's thumbnail is the loop at the top of the prefix converting the shape into that of the Zac prefix. The edge of the thumb would then be that of one of the two nubbins of the prefix of that month. This detail is not sufficiently clear to be certain, but I think there can be little doubt that the Zac prefix is here intended.

Difficulties still remain with the acceptance of the month sign as Zac, for the distance number as it stands will not connect 1 Ahau 3 Zip with Zac, or for that matter with any month of the Cauac group. Beyer has pointed out the frequency of errors in Maya long-distance calculations, and it is obvious there is an error here. However, if the katun coef-

ficient is changed from 19 to 7, the distance number joins the two dates satisfactorily:

1.11.4.12.9.0.0.0	1 Ahau 8 Zac
14.17.7.10.0.0	
1.11.19.9.16.10.0.0	1 Ahau 3 Zip

The coefficients above that of the cycle are those used on Stela 10, Tikal. Morley (1939) gives a reading of 9.17.4.0.0 10 Ahau 18 Kayab, which, he says, "may be accepted without reservation as the dedicatory date" of the last ball court at Copan. He decipheres the three last glyphs of the inscription as 10 Ahau 18 Kayab, end of Tun 4. Nevertheless, the element which he takes as a coefficient of 4 does not belong with the last glyph, but is a postfix of Kayab, as is clearly shown by the fact that it is beneath the coefficient of Kayab. Furthermore, this element is not four numerical dots, but the flame-like postfix which is almost always found with Kayab. Indeed, this element alone is sufficient to differentiate Kayab from any other month sign. It is perfectly clear in the photograph.

The first glyph seems to me to be a head in profile. In view of the month coefficient it might be Ahau, Men, or perhaps Chicchan. The last glyph resembles the tun sign, but it has a pair of superfixes which never occur with a tun sign in such a connection.

Since architectural students may base their conclusions as to the age of the ball court on epigraphic material, this reading of 9.17.4.0.0 10 Ahau 18 Kayab, although possibly correct, should be accepted with reservation. Another possibility is 9.16.10.14.15 10 Men 18 Kayab. However, it is quite likely that this is not the dedicatory date of the ball court, since it is neither at the beginning nor at the end of the inscription. As the inscription appears to close with a day sign 10 Ahau, the most likely date is 9.15.5.0.0 10 Ahau 8 Chen, for by the text occurrence of 10 Ahau at the close of a round number (9.18.10.0.0 19 Ahau 8 Zac) the Initial Series appears to have gone out of use at Copan.

The glyphs on the east face of Stela J, Copan, are arranged in an interesting mat pattern, first unraveled by Maudslay. There is some confusion as to how the pattern was followed at the base. Maudslay's numbering is certainly correct as far as No. 24, save that his Glyph Block 8 should be omitted from that sequence, and Glyph Block 25 inserted between 6 and 7.

Beyond that point there is an error, for if the glyphs are read as numbered, the distance number recorded by Glyph Blocks 31 and 32 is reversed. That distance number, as Morley pointed out, leads to the

a

38.2. Mat pattern on Stela J, Copan: (a) suggested arrangement with two strands. Circled numbers show direction uncertain; other numbers oriented to glyphs.

date 7 Lamat 1 Mol. Morley noted the presence of 7 Lamat, but failed to identify the clear 1 Mol at Glyph Block 26 because, following the Maudslay sequence, he looked for it at Glyph Block 28. Actually, it is at Glyph Block 26. This is added evidence that the sequence here has been wrongly read.

b

38.2. Mat pattern on Stela J, Copan: (b) pattern of mat motif in Maya art.

In a discussion of the sequence Miss Tatiana Proskouriakoff has suggested to me that the design is based on the use of two strands, a common motif in Maya art (Fig. 38.2b). She called attention to lines at the corners of the stela face which appear to represent the projecting ends of the strands.

On the basis of that identification, the inscription would start on Strand 1 at the top right corner and continue to the end of that strand at the bottom left corner. Thence it would pass to the start of Strand 2 at the top left corner and terminate at the end of the strand at the bottom of the right corner. The design of the stela, however, is not quite the same as the conventional intertwined pattern. Apparently all four ends of strands pass under a counterstrip before projecting (Fig. 38.2a). This is certainly true of the two top ends. The inscription starts with Glyph Block O. The orientation of Glyph Block 17 (new numeration) to top shows that it can not be part of the same sectional strip as Glyph Block 26 (orientation to top left). On the other hand, Glyph Block 25 has the same top left orientation as Glyph Block 26. The strip, therefore, must pass under 17 to emerge at 25, then pass under two strips to re-emerge at 26. This arrangement is clear on the stela itself. Similarly the sequence 31, 32, 33 is partially supported by the dividing lines around the glyph blocks. Furthermore, this arrangement is strengthened by Glyph Blocks 34 and 35, which almost certainly record a Calendar Round date. There remains only the bottom right corner, unfortunately badly damaged. The line between the projecting end and the corner glyph block is clear in the photograph. This indicates that the former is not a continuation of the latter, but that the band passes under a strip before terminating. One must conclude that Glyph Block 6 contained a head form coefficient, and Glyph Block 7 the day Ahau.

Glyph Block 34 (Maudslay's 8) has the outline of a day sign with coefficient above. Glyph Block 35 (Maudslay's 38) is drawn as a birdlike head with a coefficient of 13. Photographs show that this is probably the Cauac element of Chen, Yax, Zac, or Ceh. The superfix is gone. The two glyphs can probably be restored as 8 Ahau 13 Ceh, as called for by the calculations. The text then reads:

0-12	9.13.10.0.0	7 Ahau 3 Cumhu (I.S.)
18, 19	13.10.0.0	subtract
34, 35	9.0.0.0.0	8 Ahau 13 Ceh (?)
40, 41	6.11.12	subtract from first date
46, 47	9.13.3.6.8	7 Lamat 1 Mol

Decipherments of Copan inscriptions made since the publication of Morley's *The Inscriptions at Copan* are to be found in the following papers: Beyer 1932, 1936a, b; Long 1923; Morley 1939; Teeple 1930; Thompson 1931, 1935, 1936.

The Dating of Seven Monuments at Piedras Negras

J. Eric S. Thompson

Morley (1938) has reaped a rich harvest of skillful decipherments from the large body of hieroglyphic texts at Piedras Negras. However, fields are seldom reaped so clean that nothing is left for the gleaner, and that is the case with the Piedras Negras texts. New datings are given below for seven monuments. In the order of their decipherment these are: Stela 8, Altar 1, Stela 23, Lintel 3, Miscellaneous Sculptured Stone 16, Lintel 7, and Miscellaneous Sculptured Stone 1. In the discussion that follows readings not offered as amendments are those of Morley except for decipherments credited to Beyer, Proskouriakoff, and Satterthwaite. In tabular presentations new readings are marked with asterisks.

The text of Stela 8 opens on the left side with the Initial Series 9.11.12.7.2 2 Ik 10 Pax. A distance number of 1.2.3.9 carries the count forward to 9.12.14.10.11 9 Chuen 9 Kankin (B18-A19). Morley reads the next date (A22-B22) as (9.11.1.15.16) 12 Cib 14 Chan, a backward move of some 33 years. However, at B20 there is a glyph which resembles somewhat forms of kin used in distance numbers. This has a coefficient of 3. If we assume that this glyph represents a distance number of three days, the eroded Calendar Round date at A22-B22 can be restored as (9.12.14.10.14) 12 Ix 12 Kankin.

The last glyph (B24) on the left side is described by Morley as very unusual. Nevertheless, it is the well-known kin variant, consisting of one or two inverted Ahau over a serpent segment (Beyer 1938). As the coefficient here is plainly 3, the glyph indicates a distance number of three days. The text then passes, not

as Morley supposed to the right side of the stela, but to the front, where at E1-F1 2 Caban 15 Kankin, three days after the last date, is plainly recorded. The text for these three dates accordingly reads:

B18-A19	9.12.14.10.11	9 Chuen 9 Kankin
B20	3	
A22-B22	9.12.14.10.14	12 Ix 12 Kankin
B24	3	
E1-F1	9.12.14.10.17	2 Caban 15 Kankin

As added confirmation, it may be noted that the middle date is found also on Stela 7 at this site.

For the various dates in relief on the front of Stela 8 Morley's readings can be accepted except for the text from L3 to M2 inclusive. The glyph at L3 he reads as 2 uinals and an uncertain number of days. To judge by his drawing, the two dots above the sign may not be numerical but may be the inverted Ahau faces of the kin variant (repeated elsewhere on this stela), which consists of the "serpent segment" with one or two inverted Ahau faces above. On that assumption, the whole would record somewhere between 1 and 10 kins. An addition of 3 kins will bring the count to 9.12.14.13.4 10 Kan 2 Kayab which is precisely 1 katun earlier than the first date recorded on the right side of the stela, and 5 tuns earlier than a date recorded on Altar 1. As is well known, the astronomer-priests of Piedras Negras delighted in recording such anniversaries of dates that were not tun-endings. Unfortunately the

Calendar Round date and the subsequent Secondary Series are entirely eroded, but the above appears the most probable interpretation. At C1, the first glyph on the right side of the monument, there is a glyph which Morley reads as 2 uinals 8 kins. To get this reading he was forced reluctantly to assume that the coefficient of 8 to the left was reversed, the bar coming in front of the three dots. Such an arrangement is against all Maya tradition and practice.

Fortunately, it is not necessary to impute such an unprecedented arrangement to the Maya. There is little reason to doubt that the glyph is again the kin variant consisting of one or two inverted Ahaus over the "serpent segment," Morley's coefficient of two dots above becomes the two inverted Ahaus of that glyph, and his bar to the left can be read as a somewhat eroded count bracket, such as sometimes accompanies this glyph (cf. Glyph F3, Stela 1, Piedras Negras).

This distance number of 3 kins serves to connect 5 Imix 19 Zac, the last date in relief on the front of the stela, with 8 Kan 2 Ceh, the first date on the right side of the monument, as deciphered by Morley. The only difference is that this last date must be moved forward one Calendar Round from the position given it by Morley, viz.:

Front	U1-V1	9.13.14.13.1	5 Imix 19 Zac
Right side	C1	3	
	D1-C2	9.13.14.13.4	8 Kan 2 Ceh

Naturally, the rest of the dates on the right side of this stela must also be moved forward from the positions Morley assigned them. The last date then becomes 9.14.12.7.2 9 Ik 10 Pop.

This last date is followed in C20 by "End of count of 3 Katuns." As this date is precisely 3 katuns later than 9.11.12.7.2 2 Ik 10 Pax, the Initial Series of this text, the various interpretations here offered are certainly correct. Katun and tun anniversaries of non-tun-ending dates are frequent at Piedras Negras. The date 9.13.14.13.1 is another example on this same stela, and the Initial Series of Lintel 3 reads 9.15.18.3.13 5 Ben 16 Chen, count of 1 katun, referring to the anniversary of 9.14.18.3.13 recorded on Stela 11 and Altar 2. As a matter of fact the date 9.13.14.13.4 8 Kan 2 Ceh is also an anniversary, for it is 15 tuns after the date 9.12.19.13.4 3 Kan 17 Muan, which, as we shall see, was declared on Altar 1. There does not, however, appear to be any glyphs indicating the passage of these 15 tuns on the rather weathered surface of the right side of Stela 8. I have in preparation a paper dealing with these numerous anniversaries.

I am indebted to Miss Tatiana Proskouriakoff for the readings on the right side of this stela (except

the first distance number). She called my attention to the record of 3 katuns after 9 Ik 10 Pop, pointing out that meaning was given the record by moving the dates forward one Calendar Round from the positions favored by Morley.

The whole text of this stela accordingly reads:

Left	A1-B8	9.11.12.7.2	2 Ik 10 Pax
	A17-A18	1.2.3.9	Posterior date indicator
	B18-A19	9.12.14.10.11	9 Chuen 9 Kankin
	B20	*3	
Front	A22-B22	*9.12.14.10.14	12 Ix 12 Kankin
	B24	*3	
	E1-F1	9.12.14.10.17	2 Caban 15 Kankin
	G1	(4)	
	H1-G2	9.12.14.11.1	6 Imix 19 Kankin
	I1	2.0	
	I2-J2	9.12.14.13.1	7 Imix 19 Pax
	L3	*3	(?)
	M1-N1	*9.12.14.13.4	10 Kan 2 Kayab (?)
	M2	*4.16	(?)
	N2-N3	9.12.15.0.0	2 Ahau 13 Zip, end of tun count
	O3-P3	5.0.0	Posterior date indicator
	O4-P5	9.13.0.0.0	8 Ahau 8 Uo. End count 13 katuns
	S1-T2	14.13.1	S.S. and posterior date indicators
	U1-V2	9.13.14.13.1	5 Imix 19 Zac. End count 1 katun.
Right	C1	*3	
	D1-C2	*9.13.14.13.4	8 Kan 2 Ceh
	D7-C8	7.16.5	Posterior date indicator (?)
	D8-C9	*9.14.2.11.9	6 Muluc 7 Mol
	C13-D13	9.1.3	Posterior date indicator (?)
	C14-D14	*9.14.11.12.12	6 Eb 5 Yaxkin
	C18-D18	12.10	Posterior date indicator
	C19-C20	*9.14.12.7.2	9 Ik 10 Pop. End count 3 katuns
	D23	*(9.14.15.0.0)	11 Ahau (?)
	Y1-Y2	*(9.10.6.7.4)	4 Kan 17 Zotz
Incised glyphs on front	Y5-Y8	4.8.2.14	Posterior date indicator
	Y9-Y10*	(9.14.14.9.19)	5 Eznab 16 Zip

The question next arises as to the dedicatory date of this stela, Morley, having placed the dates on the right side of the stela one Calendar Round too early, considers 9.13.0.0.0 8 Ahau 8 Uo to be the dedicatory date of the stela. Such an ascription was open to question even with his readings, for a Secondary Series carries the count over 14 tuns beyond that date. With the new arrangement there are two dates in the second half of Katun 14, the second of which is only 162 days before 9.14.15.0.0 11 Ahau 18 Zac, and may represent a determinant thereof ($18 \text{ Zac} + 203 = 16 \text{ Zip}$; Gregorian is 200-3/4). That date is probably the dedicatory date of the stela. In fact, 11 Ahau may be inscribed at D23, the last glyph block on this side of the stela. A weathered glyph with what appears to be a day sign cartouche and trinal support is clearly visible. The coefficient is seemingly 11 or 16. As a day sign coefficient of 16 is an impossibility, the whole may read 13 Ahau, an abbreviated reference to 9.14.15.0.0 11 Ahau 18 Zac. The right half of the glyph is even more weathered. Conceivably it might be the "5 tuns lacking" glyph.

Morley speaks of Stelae 1–8 as forming a single line, but in the more recent map published by Satterthwaite ("Piedras Negras Architecture"), which includes results obtained after Parris' preliminary map was supplied Morley, Stelae 1–7 stand on a single platform, Stela 8 being detached. In his text (p. 30) Satterthwaite notes that Stelae 2–7 were set on this platform, but Stela 8 definitely was not. He remarks that there is a possibility that Stela 1 also may have been off the platform. The sequence of erection of the stelae was as follows:

Stela 6	9.12.15.0.0
2	9.13. 5.0.0
4	9.13.10.0.0
1	9.13.15.0.0
3	9.14.0.0.0
5	9.14.5.0.0
7	9.14.10.0.0
8	9.14.15.0.0

Assuming that Stelae 1–7 are on the same platform, and that the katun 9.13.0.0.0 8 Ahau 8 Uo was commemorated, like several other katun-endings at Piedras Negras, on a large altar, the sequence of stela erection would have been:

4	2	5	3	6	1	7	8
(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)

The numbers above refer to sequence of erection; those below to the designations of the stela. Stela 6 was erected first, then Stela 2 well to the left. Next Stela 4 midway between the two. Then starting on the left, Stelae 1, 3, 5, and 7 were erected in that sequence to fill the gaps at the sides of the stelae already in position. With the erection of Stela 7 the platform was filled. Accordingly, Stela 8, the last of the series, was placed by itself a little farther to the side: In view of the discovery of the detachment of Stela 8, this is a more logical arrangement than to suppose that Stela 8 was erected by itself off the platform when only one stela had been placed asymmetrically on the platform.

Morley believes that Stela 23 recorded the date 9.14.15.0.0, to which Stela 8 is now assigned. The reading of the Initial Series of Stela 23 is extremely doubtful, and, because of evidence yet to be presented, it is far from likely that that was the dedicatory date.

It is reasonably certain that Altar 1 commemorates the katun 9.13.0.0.0 8 Ahau 8 Uo, although that date is no longer visible. There are, however, excellent reasons for believing it was once inscribed on Support 2, the surface of which is now entirely eroded.

In contrast to his brilliant decipherments of most inscriptions at Piedras Negras, Morley commits several errors in deciphering the text of Altar 1. At times even Jove nods. Beyer (1943) has rectified Morley's date at S1-T2 to 8.13.0.0.0 9 Ahau 3 Zac, and this correction is here utilized.

It is simplest to start the discussion with the two dates recorded on Support 1, although these do not actually open the inscription. The first of these Morley reads 3 Muluc 17 Muan, and places thousands of years in the past. An inspection of the photograph makes it quite clear that the day sign is Kan, The looped line, the circle above, and the parallel lines below are all quite clear. A position for this date is 9.12.19.13.4 3 Kan 17 Muan, which is just 5 tuns after the restored date on the front of Stela 8, and 15 tuns before another date on that stela. At J'2 there is a winged Cauac glyph with a head coefficient to the left. The head appears to be that of the number 5 (note the tun-like headdress). There seems, therefore, little doubt that this records the end of 5 tuns from the date 9.12.14.13.4 10 Kan 2 Kayab. Next there is a day with a coefficient of 9. Morley reads this as Ahau; but the dot in the center indicates Muluc. The next glyph should be the month sign, but appears to be something different. Unfortunately the next glyph block is eroded.

At K'4-J'5 there is a Secondary Series consisting of 11–13 kins, 1–3 uinals, and a posterior date indicator. This last Morley reads as a tun sign, but

the flame-like element of the indicator can be distinguished beneath. The central dot of the uinal coefficient is a shade larger than the flanking dots, making 2 the better reading. If the kin coefficient is read as 1, the date connects with 9.13.0.0.0, viz.:

Support 1	J'1-J'2	9.12.19.13.4	3 Kan 17 Muan. 5 tuns
	K'2-J'3	(9.12.19.15.9)	9 Muluc (2 Cumhu)
	K'4-J'5	2.11	
Support 2		(9.13.0.0.0)	8 Ahua (8 Uo)

Anniversaries of the first two dates occur elsewhere at Piedras Negras (Stela 8 and Lintel 7), making it virtually certain that the decipherments are correct. Complete confirmation, however, is supplied by the Secondary Series of 19.13.4 recorded at A2. If this is counted forward from 9.12.0.0.0 10 Ahau 8 Yaxkin, the position 9.12.19.13.4 3 Kan 17 Muan will be reached. Moreover, this latter date lies immediately beneath the position held by that distance number on the perimeter. It is, accordingly, clear that the whole of the text on the perimeter should be read until B2 is reached. Then the inscription passes to Supports 1, 2, and 3 in that order.

Support 3, as Morley recognized, carries the date 10.0.0.0.0 7 Ahau 18 Zip. However, immediately before this, at N'5a there is a katun sign with a coefficient of 7. This, of course, links 9.13.0.0.0, which we have already assumed to have been on the weathered Support 2, with 10.0.0.0.0.

The whole text then reads:

Perimeter	E1-E2	9.0.0.0.0	8 Ahau 18 Pax	End 9 cycles
	J2	4.(0.0.0.0)	Add	
	K1-K2	13.0.0.0.0	4 Ahau 8 Cumhu	End 13 cycles
	Q2-R1	8.13.(0.0.0)	Add	
	S1-T2	8.13.0.0.0	9 Ahau 3 Zac	End? 13 katuns; end tun count
	A'2	*11.(0.0.0)	Add	
	C'2-D'2	9.4.0.0.0	13 Ahau 18 Yax	End count 4 katuns
	F'1a	*6.(0.0.0)	Add	
	H'1-L'1	9.10.0.0.0	1 Ahau 8 Kayab	Count? 10 katuns; End tun count
	A1a	*2.(0.0.0)	? Add	[half cycle]
	A1b	*9.12.0.0.0	12 Ahau 8 Yaxkin	?
	A2	*19.13.4	Add	
Support 1	J'1-J'2	*9.12.19.13.4	3 Kan 17 Muan	5 tuns
	K'2-J'3	*9.12.19.15.9	9 Muluc (2 Cumhu)	
	K'4-J'5	*2.11	Add	
Support 2	?	*(9.13.0.0.0)	8 Ahau 8 Uo	
Support 3	N'5a	*7.(0.0.0)	Add	
	O'5-N'6	10.0.0.0.0	7 Ahau 18 Zip	Count to 10 cycles

There is a small possibility that 9.12.0.0.0 was not recorded on this altar, but, instead, that the distance number was 2.19.13.4. This is not very probable since A1a probably records 2 katuns, and A1b appears to carry a Calendar Round date, presumably 12 Ahau 8 Yaxkin, although the text is too weathered at this point to be certain of this.

One small matter deserves attention. The glyph blocks on the perimeter are read in fours, for example K1, L1, K2, L2, then M1, N1, M2, N2, etc. However, there is a single vertical pair of glyphs I'1, I'2, which have to be read as a single group. This is clear from the fact that H'1, G'2 record 1 Ahau 8 Kayab, count 10 katuns; H'2 records end of a tun, and I'2 a clear half-cycle. Yet the next four glyphs obviously have to be read in the usual sequence.

There is a logical explanation for this. After H'2 there remained spaces for only six glyph blocks. Perhaps the last four glyph blocks at A-B had been carved, and it was necessary to fill the two uncarved glyph blocks at I'. One suspects this may have happened from the fact that 1 Ahau 8 Kayab is recorded as "Count (?) 10 katuns, end count of tun, (two eroded and unidentified glyphs), half-cycle glyph." More important dates in this text had been treated with less attention. Moreover, the hand ending sign practically never precedes the tun sign, as here. The information could well have been carved in three glyphs, but five were taken, as though expanded to fill the two extra glyph blocks, for which no provision had been made. Even the Maya may have had to justify margins.

In view of what has been written above, 9.13.0.0.0 or 10.0.0.0.0 must have been the dedicatory date of this altar. I think there can be little doubt that the former was the katun this altar commemorated for the following reasons:

On several monuments calculations lead forward from the dedicatory date to 10.0.0.0.0. Examples are Stelae J and 8, and Altar S, Copan; Temple of the Inscriptions, Palenque; Zoomorph G, Quirigua.

In the texts of Stela J, Copan, and the Temple of Inscriptions, Palenque, these recordings of Cycle 10 are combined with reckonings into the distant past, as on Altar 1, Piedras Negras.

The dates 9.4.0.0.0, 9.10.0.0.0, 9.12.0.0.0, 9.13.0.0.0, and 10.0.0.0.0, all of which occur on Altar 1, are also found on the Temple of the Inscriptions at Palenque, the dedicatory date of which was almost certainly 9.13.0.0.0.

Thirteen katuns was a sacred number. It brought memories of 13 cycles, and thereby gave an impetus to reckonings into the past and future. The commemoration of a Katun 13 gave occasion for seeking various linkages involving the number 13: 9.0.0.0.0 ends on 8 Ahau; Katun 13 falls in the next Cycle 9 and also ends on 8 Ahau. It is 13 cycles and 13 katuns later. The date 8.13.0.0.0 ends 13 katuns just one cycle earlier than 9.13.0.0.0. The katun 9.x.0.0.0 ends on 13 Ahau, and, of course, 4 Ahau 8 Cumhu ends 13 cycles.

I must express my disagreement with the thesis advanced by Morley that the Maya at Cycle 10 were more apt to make long calculations into the past. Toward the end of the cycle most matters in dispute appear to have been settled, and texts generally become shorter. It was around 9.13.0.0.0 that the liveliest discussions and the fullest research were in progress. Arguments about the length of the solar and lunar years sent the Maya priests calculating far into the past. The following texts, all dating from near 9.13.0.0.0, prove this: Tablets of the Cross, Foliated Cross, Sun, and Inscriptions at Palenque; and Altar I' and Stelae T and J, Copan. This matter has received some comment from Teeple. I consider the presence of these early dates an excellent reason for dating the altar as 9.13.0.0.0.

Lastly, one must consider the position of Altar 1. It is situated in front of Stelae 1-8, which, as we have seen, date from 9.12.15.0.0 to 9.1.15.0.0 with the exception of that one katun-ending. Furthermore, if Stela 8 was dedicated at 9.1.15.0.0 and Altar 1 at 9.13.0.4.0, every 5-tun-ending from 9.12.5.0.0 to 9.16.0.0.0 inclusive was commemorated by a monument in the plaza of the west group. Similarly dates earlier than 9.12.5.0.0 were commemorated by stelae

in the south group, and those subsequent to 9.16.0.0.0 by monuments in the east group.

In rebuttal of one of Morley's arguments for assigning Altar 1 to 14.0.0.0.0, the absence of an Initial Series, it would be well to bear in mind that the glyphs on the surface are entirely eroded. They might have carried an Initial Series. Also, should 10.0.0.0.0 be commemorated by Altar 1 with its lengthy inscription, denoting full cultural activity, where are the stelae to commemorate 9.19.5.0.4, 9.19.10.0.0, and 9.19.15.0.0?

Everything considered, there can be little doubt that Stela 8 commemorates 9.1.15.0.0; Altar 1, 9.13.0.0.0. There remains only the placement of Stela 23.

Teeple and Morley consider that the Initial Series on the left side of Stela 23 records 9.1.15.0.0 11 Ahau 18 Zac, basing this reading partly on the Initial Series introductory glyph, partly on the Initial Series itself, and partly on the moon age.

That the variable element of the Initial Series introductory glyph is that of the patron of Zac there can be little doubt, but Morley's assumption that the coefficients of the uinal and kin are zero and the further assumption that this Initial Series represents the dedicatory date of the stela are very different matters. There are two Initial Series on this stela, and, accordingly, the chance of that on the left side being the dedicatory date is less than even, for the other Initial Series or a weathered Period Ending might equally well represent the dedicatory date. Of the 36 fairly certain Initial Series at Piedras Negras, 14 do not mark the ends of 5-tun period: or their multiples. Thus the chances of an Initial Series recording a Period Ending are about three to two. More important than this, however, is the fact that the texts of monuments at Piedras Negras almost invariably start on the left side. Since the first of two Initial Series which opens a text is likely to be earlier in date, the chances of the Initial Series on the left side of a monument marking its dedicatory date are not very great.

On the right side (C16-D16) there is a date which Morley deciphers as 7 ? 17 ?, but the circle of Kan is fairly at the top of the day sign. This is followed at C24-D24 by a Secondary Series which Morley deciphers as 9 tuns, 6-13 uinals, 16 kins. The two glyphs immediately beneath them are entirely eroded. To fudge by other examples, the final date of the monument may well have been recorded on these weathered blocks.

Leaving the question of this part of the text in abeyance for the moment, let us turn to the back of the monument. Much of the inscription has gone, but a number of glyphs are in fairly good shape in the last two columns. The text closes in the middle of a

sentence, for there is a distance number of 11 uinals, 11–13 kins, and lastly the “forward-sky-earth-sun” glyph. This ultimate glyph invariably lies between distance numbers and the dates they reach. As there is no date here, it must have been recorded on the front of the stela or as one of the Initial Series. If the former, it is likely to be a date given elsewhere on the monument.

A possible reconstruction of the past of the text already discussed, together with the dates immediately anterior thereto, would be:

		*(9.17.19.2.17	7 Caban 0 Kayab)
Back	16	13.3	
	I7-J7	*9.17.19.16.0	10 Ahau 18 Zac
	K2?	*(13)	
	K3-L3	*9.17.19.16.13	10 Ben 11 Ceh
Right	K7	*11.11	
	C16	*9.18.0.10.4	7 Kan 17 Tzec
	C24-D24	*9.7.16	
	C25-D25?	*(9.18.10.0.0	10 Ahau 8 Zac)

This reconstruction, although far from proved, obtains some confirmation from the pattern of day coefficients. There are three dates with the number 10 and two with the number 7. The former includes the supposed dedicatory date. There are also two occurrences of Ahau and three occurrences of the month Zac, for the Initial Series on the left side fell in that month. As is well known the priest-astrologers of Piedras Negras were much given to such dicing with numbers, days, and months.

The coefficients of the second and third dates and the Kan sign are certain. The first distance number is sure. The uinal coefficient of the second is certain, and the day coefficient is 11, 12, or 13. The two top dots are partly eroded, the bottom one solid. A reading of 11 is possible, although 12 or 13 is somewhat better. The tun and kin coefficients of the third distance number are certain, and the uinal coefficient is 11–16 inclusive.

A dedicatory date of 8.18.10.0.0 10 Ahau B Zac for Stela 23 finds some confirmation in the location of that stela in the court of the east group, the deciphered dates of which range from 8.16.5.0.0 to 9.19.0.0.0. It is, of course, possible that the Initial Series on the left side carries the date 9.14.15.0.0 11 Ahau 18 Zac, but for reasons already given this is likely to be the earlier of the two Initial Series.

Attention might also be called to the unusual postfix of uinal glyphs on Stela 23. This suggests lateness and a relaxation of rigid standards of glyphic delineation. It may be a development of the postfix

attached to a uinal glyph on Lintel 3, which, as we shall see, probably was dedicated at 9.17.15.0.0.

The evidence for dating Stele 23 at 9.18.10.0.0 can be summarized:

1. The Initial Series on the left side is probably earlier than that on the right because of the order in which sides of stelae at Piedras Negras are almost invariably read. The text on the back breaks off in the middle of a sentence, and therefore it is most probable that the final date is given on the right side (it may have been repeated, according to a fairly common practice, on the now weathered front of the stele).
2. The last distance number on the back probably connects with a date on the right side, and a distance number forward from that can be read to reach 9.18.10.0.0.
3. The juggling with the same numbers and month name supports the interpretations given.
4. The unusual postfix of uinal signs suggests lateness.
5. The location of the stele calls for a late date, one after 9.16.0.0.0.

For the above reasons it is not improbable that Stele 23 was dedicated at 9.18.10.0.0 10 Ahau 8 Zac.

In view of the new dates for Stela 8 and Altar 1 and the probable dedicatory date of Stele 23, it is apparent that in all likelihood no monument was erected at Piedras Negras in a group to which it did not chronologically belong. The monuments are arranged as follows:

9. 4.0.0.0? to 9.12.0.0.0	south group
9.12.5.0.0 to 9.16.0.0.0	west group
9.16.5.0.0 to 9.19.0.0.0	east group

The various dates deciphered by Morley on the beautiful Lintel 3 at Piedras Negras do not reach a tun-ending. The latest found by him is 9.16.6.12.0 10 Ahau 3 Pax, and he concludes that the lintel commemorated 9.16.10.0.0, that half-katun-ending being, he believes, inscribed on Lintel 3.

It is very probable that the dedicatory date of Lintel 3 was a katun later or 25 tuns later.

At U7-V7 there is a distance number which appears to have escaped Morley’s notice. Beyer (1942) calls attention to it without attempting its decipherment. The katun and tun signs with coefficients of 1 and 4 respectively are very clear. The coefficients of the uinal sign are badly eroded. At U8 there is the “forward-sky-earth-sun” glyph, such as frequently lies between distance numbers and dates at Piedras Negras. The details are weathered, but

enough remains to make the identification plain. This is followed in V8 by the day Imix with a blurred coefficient and the month Zip, also with a blurred coefficient. It is, however, clear that both coefficients are high. The only reconstruction which will fit the data is:

V4-U5	9.16.6.12.0	10 Ahau 3 Pax
U7-U8	*1.4.12.1	Forward-sky-earth-sun symbol
V8	*9.17.11.6.1	12 Imix 19 Zip

The date 9.17.11.6.1 3 Imix 19 Zip is just one tun after a date on Throne 1, 9.17.10.6.1 3 Imix 4 Zotz. Furthermore, there are close similarities in hieroglyphs between the two inscriptions. The last four glyphs of Lintel 3 (U11-V12) are almost surely repeated in that order on Throne 1 (I'3-J'4).

Lintel 3 (the designation is retained, although Satterthwaite doubts that it is actually a lintel) was connected with Structure 0-13. The terrace on which this structure stands supported Stelae 15 and 12. These record respectively 9.17.15.0.0 and 9.18.5.0.0 (9.18.0.0.0 is carried by Altar 4 in the center of the plaza). On the assumption that Stelae 15 and 12 were erected shortly after the completion of Structure 0-13, it is reasonable to suppose that Lintel 3 was dedicated to commemorate 9.17.10.0.0 or 9.17.15.0.0. The first would be rather over a tun before the, last date recorded; the latter somewhat under tuns later. Most generally the latest non-tun-ending date in a text is earlier than the dedicatory date. Although this is not a hard and fast rule, it is so generally observed that it tips the balance somewhat in favor of 9.17.15.0.0 5 Ahau 3 Muan as the dedicatory date of the lintel.

Satterthwaite (1940) describes and illustrates part of a monument which bears the designation Miscellaneous Sculptured Stone 16. He thinks this may have been a small stela. The inscription opens with a Calendar Round date, which he reads as 8 Manik 0 Ceh, giving information from Morley for this interpretation. However, the element before the month Ceh is not the spectacle glyph but the tun variant which it has been shown indicates completion. To the five examples I have discussed elsewhere (Thompson 1935b, 1943) may be added two more: this example on Miscellaneous Sculptured Stone 16, and one on the Hieroglyphic Stairway, Naranjo.

For this example at Piedras Negras there are no distance numbers to place the date in the Long Count. For the Naranjo case, the position in the Long Count is certain, but the glyphs are somewhat weathered. The reconstruction is as follows:

A1	9.10.3.2.12	2 Eb, Uayeb completed
U1	1.13.10	
V1	9.10.4.16.2	8 Ik 5 Kankin

The calculations are completely clear except for the sign which I read as Uayeb completed at A1b. This is where the month sign should be. It certainly is not Pop. The main element is a fairly clean tun, but the elements which form the superfix are hard to distinguish. Possibly only the superfix of Uayeb is present, the whole indicating the completion of the 365-day year.

The date on Miscellaneous Sculptured Stone 16 must be 8 Manik, Ceh completed, which is the equivalent of 8 Manik 0 Mac. Positions which this could have occupied are:

9.12.3.6.7	8 Manik	Ceh completed (or 0 Mac)
9.14.16.1.7	8 Manik	Ceh completed (or 0 Mac)
9.17.8.14.7	8 Manik	Ceh completed (or 0 Mac)

The Cauac element is poorly preserved, but the angularity of the infix to the right eliminates any earlier reading than the first (in early inscriptions this element is rounded.). As Satterthwaite believes that this sculpture was re-used in Structure 0-13, a date later than the third reading is impossible. Indeed, the third reading itself is for that reason unlikely, for Structure 0-13, as we have seen, was probably dedicated at 9.17.15.0.0. The sculpture would have been brand new at the time it was broken up unless one is to assume that it broke while being made or was not considered satisfactory for one reason or another; the roughness of the surface might give some support to such an assumption).

None of the three possibilities is an anniversary of some other known date at Piedras Negras, and our knowledge of the accompanying glyphs does not help us to choose between them.

By the use of anniversaries it is possible to suggest a fairly certain dating for Lintel 7. The Initial Series of this monument is 9.9.8.0.?, but there can be no question of that being the contemporaneous date. Morley considers the lintel was dedicated at 9.12.10.0.0, but there is some evidence that the dedicatory date was probably 9.14.5.0.0.

Much of the inscription is entirely gone, but in the last column of glyphs readings are obtainable. Glyph Block XI4 is the Secondary Series introductory glyph. This is followed in Y14-X15 by a distance number of 5 kins 11 uinals. Morley reads the latter as 11 Chuen, but in view of the introductory glyph and the absence of any corresponding month sign it

is virtually certain that the glyph is the rather similar uinal sign. X16-X17, as Morley notes, unmistakably records 7 Ahau 8 Kayab.

Employing a position for 7 Ahau 8 Kayab two Calendar Rounds later than that preferred by Morley, the following decipherment is obtained:

	*9.14.4.15.9	13 Muluc 17 Zac
X14-X15	*5.11	
X16-X17	9.14.5.3.0	7 Ahau 8 Kayab

The first date is 1 katun and 5 tuns after the date 9.12.19.15.9 9 Muluc 2 Cumhu recorded on Altar 1, an arrangement precisely similar to 9.13.14.13.4 8 Kan 2 Ceh on Stela 8 which is 1 katun 5 tuns after the date 9.12.19.13.4 3 Kan 17 Muan, inscribed on Altar 1 immediately adjacent to the 9 Muluc 2 Cumhu date. Since this double 25-tun anniversary can hardly be coincidental, it is virtually certain that the last dates of Lintel 7 are as given above. Conceivably X8 carries 13 Muluc, but this is far from likely.

The dedicatory date of Lintel 7, therefore, is quite probably 9.1.4.5.0.0. The sophisticated treatment of the subject matter is in agreement with such dating.

Miscellaneous Sculptured Stone 1 has a fragmentary Initial Series, the uinals and kins not hav-

ing been recovered. Morley suggests filling these as 5 and 9 to obtain the reading 9.10.6.5.9 8 Muluc 2 Zip, although he notes that the variable element in the Initial Series introductory glyph is not that of the month Zip.

Actually that variable element is the youthful head of the patron (or patroness) of the month Kayab. As the date 9.10.6.2.1 5 Imix 19 Kayab occurs on Lintel 4, and has its katun anniversary on Lintel 2, we can be reasonably sure that that was the date commemorated on Miscellaneous Sculptured Stone 1.

For the benefit of nonspecialists in Maya hieroglyphs who may desire to utilize Piedras Negras inscriptions, there are listed below scattered papers containing amended or new readings of Piedras Negras texts which have appeared since the publication of Morley's *Inscriptions of the Peten* (1938).

- Stela 12 (Beyer 1940)
- Stela 14 (Satterthwaite 1943; Thompson 1943)
- Stela 38 (Andrews 1942)
- Altar 1 (Beyer 1943)
- Lintel 2 (Beyer 1939)
- Miscellaneous Sculptured Stone 16 (Satterthwaite 1940)
- Jade head (Proskouriakoff in press)

Archaeological Finds near Douglas, British Honduras

A. Hamilton Anderson and Herbert J. Cook

In building the road from San Pablo westward to Douglas in northern British Honduras, workmen used soil dug from two Indian mounds, in the larger of which they penetrated two chambers containing skeletal material and pottery. These mounds form part of the site of Noh Mul, partially excavated by T. Gann.

When A. H. Anderson arrived on the scene, he discovered that the first mound was in the nature of a fairly extensive platform, about 4.5 m above the surrounding land and composed of marl and limestone. Accurate observation of the whole mound is exceedingly difficult because of the heavy bush which covers it. Since it was easier to take spoil from the second and larger mound, very little of the first was cut away, and in the process only a few vessels were found, of which the most notable, a black ware bowl, was stolen by a laborer.

The second mound rises about 7.5 m above the road; but on the northern side, where it slopes steeply down to the swamp, the height is nearer 15 m. The present conical shape is no doubt due to the piles of debris thrown out during the digging of a shaft from the summit under Gann's direction some years ago. It is possible that this mound is referred to as Mound 9 at Noh Mul (Gann and Gann 1939). This shaft exposes a section of stucco-faced wall, running east-west, with the exposed surface towards the center of the mound. From the edge of the wall to the outer edge of the mound is about 3 m; the top of the wall, about 3–3.5 m below the apex of the mound, is slightly convex. The stucco is now stained a deep lichenous

green which must have obliterated any paintwork it may have borne. Subsequently, M. Castillo, who dug the shaft for Gann, has stated that the surface of the wall was covered with red painted figures.

The shaft also reveals that the upper portion of the mound was constructed with roughly squared limestone blocks and mortar.

The road cutting is 1.5–1.8 m deep over this mound, and on each side is a bay from which spoil is dug. The chamber in which the polychrome dishes were found was in the bay on the southern side, and the other chamber was in the northern bay. Skeletal material was in both chambers but was not retained for examination. The foreman stated that one of the painted dishes, a very fine specimen, had an inverted dish standing in it, but apart from this nothing could be learned of the contents or size of the chambers. Since the spoil was not searched, it is not surprising that no jade or flint objects were reported. Only one small fragment of obsidian was found by the foreman.

Both chambers had been completely demolished before Anderson could reach the site. The laborers had crowded into the chambers, in spite of orders to the contrary, and had smashed most of the dishes. They still foolishly believe that Indian mounds contain gold, and their greed has been the cause of the destruction of much useful archaeological material. This vandalism had occurred while the foreman was away, and at his return he had the good sense to collect as many of the broken pieces of pottery as he could. Many of the fragments had already been

40.2 (*previous page*). Dishes, bowls, and jars: **(a)** exterior, worn red slip with legs and base unclipped; interior slipped red; tetrapod; **(b)** exterior, orange-red with legs and base unclipped; interior slipped red; tetrapod; **(c)** exterior, red on orange; interior, orange slip; **(d)** exterior, red and black on orange; interior, orange slip with red lip; two sherds between *d* and *e* illustrated in Fig. 40.4d, g; **(e)** exterior and interior slipped red; base unslipped; **(f)** exterior and interior slipped orange-red; base and legs unslipped; tetrapod (see Fig. 40.3a, e); **(g)** exterior and interior slipped red; **(h)** exterior black (?) on red; red slip continues to tops of four legs; interior slipped red; **(i)** exterior and interior, red and black on orange; base and four legs unslipped; **(j)** orange on unclipped paste both exterior and interior; **(k, m)** eccentric flints; length of *k*, 14 cm; **(l)** tetrapod bowl with orange slip (see Fig. 40.1k); design reminiscent of that of Usulutun ware, but lines more consistently parallel than is usual in that ware; perhaps made by wiping wet slip with multiple-pointed instrument, in which case it is not a true Usulutun technique; edges of individual lines more sharply defined than in most Usulutun ware (see Fig. 40.3c). Diameters, respectively, of all except flints: 25, 20.5, 22.5, 26, 25, 27, 16, 30, 24.5, 25, and 33 cm; heights, respectively: 8, 11, 11, 10, 8.5, 11, 12, 12, 8.5, and 11.5 cm.

40.3. Vessel shapes and designs: **(a, e)** shape and decoration of tetrapod dish in Fig. 40.2f; **(b)** tetrapod dish; orange slip with red lip and circle around bottom of sides; diameter 29 cm; **(c)** shape of tetrapod dish in Figs. 40.1k and 40.22l; **(d)** shape of vessel from which designs are shown in Fig. 40.4e; **(f, g)** shape and decoration of bowl in Fig. 40.1c; **(h)** form of vessel shown in Fig. 40.4b.

40.4. Basal-flanged bowl designs; water colors by H. J. Cook: (a) Design on interior of Fig. 40.1d; repeated on opposite side; (b) interior and exterior, red and black on orange; water colors illustrate design on base and on sides (same inside and out) and simple pattern on flange; (c) design on exterior of Fig. 40.1e; repeated on opposite side; (d) sherd attributable to a later period; red and black on buff; diameter of complete vessel 15 cm (see sherds between Fig. 40.2d and e); (e) interior slipped red; exterior, red and black and a light gray on unslipped buff surface; three top watercolors show design on exterior sides; the sequence was first, second, third, second; design at bottom is from basal flange; diameter 34 cm; (f) design on interior of base of Fig. 40.1i; (g) sherd of figure-painted vase; clearly not of same period as complete vessels; red, black, and gray on buff; diameter of complete vessel, 15 cm (see sherds between Fig. 40.2d and e).

carted away, and now lie buried somewhere in the roadbed. Anderson brought several hundred pieces of broken pottery back for cleaning and examination; but in spite of much patient piecing together, very few of the dishes can be reconstructed.

By probing into the cuts on the northern side, behind where the chamber had been, Anderson discovered another chamber, cylindrical in shape, measuring roughly 80 cm in diameter by 1.75 m. About 50 cm down was the skull of a child, seven or eight years of age. Fifteen cm lower and slightly to the left

of the skull, arm and leg bones came to light. A little lower still appeared a legless metate which appears to have been reworked into a toy (?) metate. No hand or foot or pelvic bones were found, but there were traces of a secondary burial among rib material discovered above the skull. All the bones were extremely friable and could not be removed intact. The chamber had no capstone over its mouth. The extreme hardness of the argillaceous earth filling suggests that it was rammed or tamped, probably to prevent the platform floor from settling.

Behind the chamber was found a T-shaped chert tool, either in the platform floor or in the debris on it.

Some time later, as the spoiling of the mound continued, another chamber was unearthed. Again the foreman tried to preserve it, but the throng of laborers caused the walls to collapse on him. Dishes were broken by this fall and by subsequent vandalism. From the foreman's information, it seems that the upper part of the mound had been raised over another building, which had been turned into burial chambers. One of these contained a skeleton lying full length, with pottery and eccentric flints alongside. One jar with a cover contained a red paint like substance. A polychrome dish with another inverted over it also stood near the skeleton. The foreman salvaged as many pieces as he could, including several jade beads and part of an annular jade ornament. The "paint pot" disappeared.

Thus, we have very little accurate information on what may have proved a valuable site. Many of the dishes remain incomplete, although most were

whole (apart from the small hole in the center) when found; but even so, details of their position have been unobtainable. There appear to be no scutate lids nor remains of tripod cylindrical vases. Besides the vessels photographed or listed, there are only some very large dishes of rather coarse ware, approximately 50 cm diameter. Only the most significant vessels are illustrated. Because of war time conditions many monochrome vessels have not been mended.

It is clear that all the pottery, with the exception of the two sherds shown in Figure 40.4d, g, is attributable to the Holmul I phase and perhaps to the Tzakol-San Jose II phase. The two sherds surely belong to the Tepeu-San Jose III phase. Material excavated by Dr. and Mrs. Gann at Noh Mul is largely of the same two phases.

We believe that the design of wavy lines arranged vertically has not hitherto been reported on the basal-flanged bowl horizon. Possibly this represents a decorative element evolved locally.

The collection under discussion is on exhibition in the Jubilee Museum, Belize.

BELIZE, BRITISH HONDURAS

The Vienna Dictionary

Ralph L. Roys

In the National Library at Vienna a Spanish-Maya dictionary of considerable importance has come to light in recent years. Miss Eulalia Guzman is reported to have discovered this manuscript, for a photostatic copy of which we are indebted to S. G. Morley.

The first page bears the title "Bocabulario De mayathan por su abecario," followed by the heading "A, ante, B." At the top of the page above the title is written "de Diego Rejon" in a hand which appears to be much later than the manuscript itself. On the last page of the manuscript in the same hand is the notation "Este Bocabulario de lengua Maya es de Diego Rejon / Rejon Arias," so it would appear that this person was a later owner and not the author of the work.

The dictionary consists of 199 numbered folios. One, written only on one side, is cut to a third of its size, and three other pages are blank; but there appears to be no break in the sequence of the contents. Consequently the dictionary, as it stands, consists of approximately 393 pages. Probably one folio is missing at the end, since the last word is *vino*. To judge by Molina's "Vocabulario de la lengua Mexicana," little more than a single page would be needed to complete the dictionary. Following f. 199 is a folio numbered "I" containing a few miscellaneous notes.

As yet I have been unable to learn anything of the authorship or history of this book; nor have I any precise information as to the size of the pages. The reproduction, which is approximately 14.5 by

21 cm, has evidently been somewhat reduced, perhaps by one-quarter or one-third. In any case there are usually 34 or 35 lines to the page. The first thirty-seven folios are written in double columns, but in the remainder of the book the items often occupy almost the entire width of the page, since the margins are narrow.

There are probably about 13,000 items, but it is difficult to determine the size of the vocabulary represented without making an actual count. In many cases a Maya expression illustrating the use of the word is a part of the item, but often the example is listed separately. As a rough estimate I think there may be approximately 10,500 words; but when the same Spanish word has various meanings expressed by different Maya words and is repeated in separate items, I have treated each of these items as a different word. Consequently this is rather an estimate of the Maya words presented than of the Spanish. One gets the impression that the author's knowledge of Maya words was more ample than his Spanish vocabulary, although the extreme simplification of the latter may have been intentional. The following extract is typical of many parts of the book.

conçertar los gueços (to set bones). pak bac.
pasivo. paakal bac.

conçertaronle los gueços. paaki u bacel.

conçertador de gueços. ah paak bac.

conçertar poniendo en orden (to regulate, setting in order). tzol ah ob. [Here the principal

parts of the verb are indicated. Colonial grammarians would consider *tzol* the infinitive, *tzolah* the “preterito perfecto,” and *tzolob* the “futuro imperfecto.”]

conçertada cosa asi. tzolan. pasivo. tzoolol.

conçertar y concordar en to que diçe (to agree in what one says). hunppelili than. conçertarse o yguarse en el preçio (to agree on a price). Ch'imba. choiba. [Apparently chimba and ch'oiba are intended.]

conçerteme asi con Juan por dos reales. in ch'imtah [chimtahl] in ba yetel Juan ti cappel tomin.

conçertar o tratar de halter algun mal y el tal conçierto (to agree on or to discuss doing some mischief and such an agreement). keban than.

conçertarse. con otro (to concert with another). accunah than etel.

conçiertate con Juan ahcunah than yetel Juan.

conçertarse con otro y haçer conçierto y amistad (to concert with another and make an agreement and friendship). kax than. kax caan.

conçierto y pacto haçerla [sic] (to make a concert and pact) xot than

conçertame con mis ojos. in kaxma in than yetel in ich (my speech agrees with my eyes [?]).

conçertar y apalabrar a la muger para que se case (to arrange and speak for a woman to marry) uinic. t[ah] te].

he conertada [sic] asi con Juana co[n] mi hijo (I have made such an arrangement with Juana for my son), tin uinictah Juana tin mehen.

conçertar un muchacho, con una muchacha para quando tenga edad (to conclude an agreement for a boy with a girl when they shall come of age), pedz ah ob.

he conçertado asi a mi hijo. con la hija. de Juan. in pedzah yxmehen tin mehen.

conçerto mi hijo con su hija. u pedzah in mehen tial.

conçertadamente hablar (to speak in an orderly fashion). hunhunppelcunabil than.

conçertado que viven con orden y conçierto (living together in order and harmony), bean.

conçertado en sus sermones. bean a tzeç, bean a can bean a than. [Literally: orderly and consistent are his admonitions, his teaching, and his speech.]

On the first 75 and the last 178 pages the writing is so similar that it is probably by the same person. The remaining third of the manuscript is in several hands. Barrera Vasquez believes that it dates possibly from the end of the seventeenth century. I am unable to judge by the calligraphy, but since the several hands suggest that it is a copy, I am inclined to ascribe the original to the first part of the same century. The mention of the caciqueship as a temporary office would appear to indicate that it was little, if any, older; but the names of various pagan deities and dances and the descriptions of flint working suggest that it dates from a fairly early period. (Barrera Vasquez 1943; Roys 1943:125, 139–40).

For one untrained in the technique of lexicography it is difficult to make a valid comparison of the Vienna with the other Maya dictionaries; and I can discuss it only from the standpoint of a student of the Maya language and literature.

Besides the well-known Motul dictionary, of which the Maya Spanish portion (hereinafter called Motul I) is supposed to have been written originally during the last quarter of the sixteenth century, three others have come down to us from colonial times. Two of them, the San Francisco and the Spanish-Maya part of the Motul (Motul II), might be tentatively ascribed to the middle of the seventeenth century. The third, named the Ticul dictionary from the town in which it was discovered, bore the date 1690. A Spanish-Maya dictionary by Alonso de Solana and dating from the sixteenth century is also reported to have survived, but it has never been accessible for study. All these, as well as other colonial dictionaries which have disappeared, are described and discussed in detail by A. M. Tozzer (1921).

Martinez Hernandez (1929:xvii), the editor of Motul I, believes that it was written by Antonio Ciudad Real, who lived in Yucatan from 1573 until his death in 1617. He was a well-known scholar and is reported to have spent forty years in the task of writing an enormous Maya lexicon; and it is hard to believe that another Maya-Spanish dictionary as large as Motul I would be compiled during the same period. The authorship of the other surviving colonial dictionaries is most uncertain.

The oldest and best of the Maya dictionaries that have been preserved is Motul I, which has been described and discussed by various writers during the past seventy-four years. It gives the Spanish equivalents of perhaps 17,000 Maya words, but its special merit is its wealth of examples. Moreover, it contains a large number of old words and phrases, which went out of ordinary use after the sixteenth century but survived in the native rituals and prophecies.

The San Francisco dictionary consists of two parts, one Maya-Spanish and the other Spanish-Maya, although the two do not closely correspond. The original, which has been lost, was copied and extensively amended by Pio Perez, who is reported to have supplied several missing pages from the Ticul, modernized the alphabetical order and the spelling of some of the Spanish words, and made various corrections. The most serious change is in the Maya-Spanish part, where he combined all the words beginning with *h* into a single group. In the original, as in Motul I, the words commencing with the aspirated "*h recia*" were separated from the "*h simple*" which is said to have been unaspirated. The Spanish-Maya part contains a little over 9000 words. Although the Maya-Spanish portion is almost as voluminous as the other, my tentative estimate shows a vocabulary of only about 5000 words, the difference being largely due to its numerous examples.

Martinez Hernandez ("Diccionario de Motul," p. xv), Berendt (MS. introduction to "Diccionario de San Francisco," p. vi), and Tozzer (1921:173) discuss this matter at greater length. The Spanish-Maya portion of the San Francisco has an appendix containing lists of numerals, adverbs of time, numerical particles, relationship terms, and parts of the body: Berendt made a copy from that of Pio Perez. By comparing the Maya-Spanish part with a still earlier partial copy by J. M. Meneses, he was able to distinguish between the words beginning with the aspirated *h* and those with the "*h simple*."

The Ticul was the first old dictionary to fall into the hands of a modern investigator. It contains about 6,000 Spanish words followed by their Maya equivalents, presented in the shortest possible form and with very few examples of their use. The original, found at Ticul in 1836, is lost, and we know it only through a much-edited copy by Pio Perez, which has been published in the same volume (1898) with a vocabulary extracted from Beltran's works. Berendt reports that the original title was "*Vocabulario de la lengua Maya que comienza en romance, compuesto de varios autores de esta lengua.*"

Of these dictionaries only the Ticul and the Maya-Spanish part of the Motul have been published. A still earlier Maya lexicon ascribed to Villalpando is believed to have been printed in Mexico in the sixteenth century. A copy of this book is reported to be still in existence, but nothing is known of its whereabouts. In 1882 Alphonse Pinart reported that he had acquired a copy published in Mexico City in 1577 (León 1905).

About the middle of the nineteenth century Juan Pio Perez compiled for publication a Maya-Spanish dictionary from the material available at the time.

The latter consisted largely of the San Francisco, the Ticul, and the eighteenth-century grammar and other works of Beltran de Santa Rosa. This was supplemented by a number of words which he apparently got directly from the Indians. Brinton appraises its vocabulary at about 20,000 words, and it is certainly no less; my own rough estimate is around 23,000 items. Pio Perez (1866–1877) unfortunately omitted some of the Maya words and most of the examples in the San Francisco dictionary, but it is nevertheless a well-edited and very useful work.

I believe that to the linguistic student and the ethnologist the Vienna dictionary is second only to Motul I in importance. In spite of the difference in size and the fact that one is Spanish-Maya and the other is Maya-Spanish, they seem very similar in conception and purpose. The difference in phraseology, however, would indicate that they are not by the same author, and each is a valuable supplement to the other. It is from these two dictionaries, from Coronel's small Maya grammar, and from a brief series of Maya documents actually written by Indian scribes between 1557 and 1600 that we are able to form some idea of the language as it was at a time when hieroglyphic writing was still in use.

The Maya grammars, or artes, composed by some of the best Franciscan linguists for the instruction of newly arrived missionaries, have been severely criticized by modern scholars. They contain translations of the paradigms from a Latin grammar into Maya. For verbs four regular conjugations were compiled, which include the subjunctive mood, pluperfect and future perfect tenses, gerunds, supines, and participles, but the aspects of the verbs seem to be little recognized. Naturally these writers missed the spirit of the language in their treatises, although a number of them are known to have spoken it idiomatically. Coronel, San Buenaventura, and Beltran de Santa Rosa, I think, were aware of this failure, for they sought to remedy the deficiency by numerous explanations.

Once the pupil had learned the forms in the arte and had acquired a fair-sized vocabulary and some mastery of the difficult phonetics of the language, he could probably make himself understood. Such a manner of speaking, however, would hardly enhance his prestige, especially among the upper class, who continued to occupy a position of social and local political importance. Much more could be learned through conversation, but books of reference were needed, especially for the preparation of a sermon. The Vienna and Motul dictionaries with their wealth of examples of polished diction, would supply the deficiencies of the grammars, and it seems obvious that they were so intended.

As we have seen, the Vienna manuscript is not much more than half the size of the great Motul I. Naturally it has not the vocabulary of the latter, nor are the uses of the words so profusely illustrated. Moreover, it is less carefully arranged and coordinated than the Motul, where the examples are practically always a part of the item headed by the word under discussion. The only really serious failing of the Vienna is its spelling of Maya words. The orthography of Motul I is riot impeccable, but errors are comparatively rare and confined largely to Spanish words. In the Vienna misspelled Maya words are fairly frequent. Very often *c* is substituted for the *k*, which designates a glottalized palatal in the Yucatecan notation, and *ch* for a certain emphatic articulation of this sound, distinguished in the Yucatecan notation by adding a cross bar to the shaft of the *h*. (In the present study it is indicated by *ch'*.) These are by no means merely academic distinctions; they seriously affect the meaning of the word. Other typical errors are *chabac* for *chauac* ("long") and *cum* for *çum* ("rope").

These mistakes, which may well be the fault of copyists and not of the author, are apparently due to carelessness rather than to ignorance, for the misspelled words are written correctly elsewhere, sometimes even on the same page. For the linguistic student this is a source of uncertainty, unless he can check the word in another dictionary or in a reliable Maya text.

Nevertheless, in spite of these errors, the book is a most valuable aid to the translator of the older Maya texts.

Except for the Motul, which mentions the rain god and that of the underworld, the Vienna is the only dictionary that pays much attention to the pagan deities. To these the missionaries applied the term *cizin* ("devil"), but I believe that in pre-Spanish times it was applied chiefly to gods of the lower regions, and perhaps also to evil spirits. In this connection the following extracts from the Vienna manuscript are of interest:

To idolize (ydolatrar): *kul cizin* ("worship the devil"), *ciz inyah*, *cizinil than* ("devil talk"), *tanlah cizin* ("serve the devil").

To idolize, burning incense to the idol or devil: *toc pan [pom] ti cizin*. [*Pom* is copal gum.]

Idol (ydolo) or image, representation of the devil: *a uinbail cizin*.

Idol, statue which is adored: *culche*, *a uich ku* ("the face of the god").

Idols and gods of the heathen: *kuulob* ("gods").

Idol of clay, the idolaters call it *lac*. [Primarily a shallow bowl. The term has been applied to effigy incensarios, but I do not know that it designated other clay figures.]

Old idols, when they had made other new ones: *hel lac*. [*Hel* usually means "something different."]

To make idols: *pat cizin*, *pat culche*. [*Culche* usually means a wooden image and *pat*, to shave a plastic material.]

Idol of clay: *patbil kat* ("shaped clay"); of wood: *polbil the* ("carved wood"); *thohbil turiich* ("hewn stone").

Principal idol [god], which these Indians of this land had, from which they said all things proceeded and who was incorporeal; hence they made no image of him: *Colop-u-uich-kin*. [*U uich kin* means "face or eye of the sun." Other writers thus describe a deity named Hunabku, "one and only god."]

Idol said to be of the preceding: *Hun Itzamna*, *Yax-cocah-mut*. [Possibly the son of *Colop-u-uich-kin* is meant here.]

Another idol, who was a man and whom they worshipped for having discovered the art of the letters of this land: *Itzamna*, *Kinch-ahau* ("sun-faced or sun-eyed ruler").

Idol of the rain, of the maize (panes), of the thunder and lightning: *Chac*.

Idols of the chase: *Acanum* [cf. *Landa's* *Acanum*, a hunting deity], *Ah Tabay* ("deceiver" or "snarer"), *Ku-bolay*, *Ceh-lac*. [*Ku* means god and *bolay*, a beast of prey. *Ceh-lac* suggests a clay effigy of a deer.]

Idol of Cozumel, whom they painted with an arrow in his hand: *Ah Hulane*, *Ah Hulneb* ("he who pierces with an arrow or dart"?).

Idols that the ancients had at the site of Merida: *Uaclom-chaan*.

Another idol of the Indians of Merida: *Ah Chuncaan*; and this was the name of the *ku*, or large hill, behind San Francisco to the east.

Idol of cruelties, to whom the people of Campeche sacrificed human blood: *Kinchahaban*, *Kinch-ahau-haban*. [This and the three preceding items are very similar to descriptions given by *Lopez de Cogolludo*.]

Idol of the people of Campeche: *Moco*. Other idols; *Ah Bolon Ahau*, *Ah Bolonil*. [*Bolon* means "nine."]

As might be expected in dictionaries intended for the use of missionary workers, the subject of sin does not suffer from neglect. We find three general terms: *tanal*, *zipil*, and *keban*. *Tanal*, which was also the Manche Chol word for transgression, went out of use fairly early in Yucatan. It is already called an "old word" in the Motul, and we no longer find it in the Ticul or in Beltran's grammar. It is defined as "sin and misery generally." Although the friars used the terms *zipil* and *keban* more or less indiscriminately, there appears to have been a distinction between them in the native mind. *Zipil* could also designate error, fault or defect, sometimes even an innocent mistake. It is harder to determine the fundamental meaning of *keban*; but one gets the idea of more deliberate wrongdoing, especially from certain compounds. *Keban than*, literally "sin talk," is defined as "conspiracy," "treachery," or "calumny."

Both the Motul and the Vienna contain an extensive catalogue of sins including many of the flesh. For a number of the latter, as well as other words pertaining to sex, there was a double nomenclature. The Motul pays more attention to this aspect of the language, but it is not entirely neglected in the Vienna. One set of words was considered vulgar or obscene, but the other category was quite respectable. Such information enabled the newly arrived missionary not only to understand the confession of a rude or an ignorant penitent but also to discuss the matter, when necessary, in grave and dignified language. To a preacher who had not grown up in the country some instruction in improper language was indeed necessary, for a neglect to glottalize a single consonant might well have a disastrous effect. The numerical classifier peel is among the most frequently used words in the language, but a failure to give it an emphatic articulation achieves a result which the lexicographer defines in Latin. It is difficult to reconcile the references to homosexual practice in these books with Landa's statement that Yucatan was free from the *pecado nefando*. I do believe, however, that the latter was not prevalent. One of the early Xiu rulers is reported to have burned a culprit in a furnace for this offence. The sexual mores in early colonial times are not without some historical significance, in view of the native accounts of certain immoral foreign invaders and the problematic origin of the very small amount of pornographic art that has been found in Yucatan.

As in the Motul, Maya plant names are well represented in the Vienna manuscript. Besides those listed under Spanish names which had been applied largely because of some real or fancied resemblance to an Old World species, about seventy-five are grouped under such general headings as *yerba*

("plant" or "herb"), *arbol* ("tree"), *bejuco* ("vine"), palms etc. About 60 percent of these are not in the Motul, so in this respect the Vienna is an important supplement to the other. Most of these names are either known to the modern Indians or to be found in other colonial sources, such as the Maya medical literature of the eighteenth century (Roys 1931). However, such early accounts of the use of many of these plants and trees constitute a valuable basis for the comparison of sixteenth-century medical practice and material culture with late colonial and modern times. It must be admitted that in the Motul the names are more carefully written and the comments more ample than in the Vienna manuscript.

The wealth of fauna names in the Vienna is also an important supplement to the information contained in the Motul. Here, are new names that I have not been able to find in any of the other dictionaries. These are sometimes of especial value in translating an obscure Maya text. The meaning of *itzam*, associated with the names of two important cities, the sky god Itzamna, and the mythological monster Itzamkab-ain, had long been surmised, since Izamal was said to signify "the place of iguanas" (*Relaciones de Yucatan* 1898-1900:1:270); but it is only in the Vienna that we find it specifically defined as "lizards like iguanas, of land and water." In the Books of Chilam Balam the frequently repeated word *bulcum* was long a problem. Often associated with the blowfly, *yaxcach*, it was evident from the contexts that it represented death by violence or massacre; and I thought it must be a word signifying slaughter (Roys 1933:103). In the Vienna, however, it is defined simply as "a large hairy fly." Here also some fourteen different names for worms, caterpillars, or grubs are to be found under the headings *gusanos* or *gusanillos*; and there are similar, though shorter, lists of ants and spiders.

The Vienna dictionary, like the Motul, reflects a period of transition from what was essentially a stone age to one of metal. Here we find words for both flint working and horseshoeing, and for the musket as well as for spear, bow and arrow, and blowgun. There had been a little gold and copper, but *mazcab*, the original word for copper, is now also applied to iron in general and to machete in particular, and *chachac* (red) *mazcab* has become the special term for copper. Gold had always been called *takin*; now silver is either given the same name or called *zac* (white) *takin*, and gold is sometimes called *kankan* (yellow) *takin*. The first Spaniards were given a few silver objects in Mexico, but I have not found any mention of it in pre-Spanish Yucatan. Lead or some dull metal resembling it may have existed, however, for in the Vienna manuscript it is named *tau* or *ek* (black) *tau*, while tin is called *zac* (white)

tau. Apparently it is an old word for just as *ta-kin* can be translated as "excrement of the sun," so *ta-u* could mean "excrement of the moon." Thompson (1939:176) reports two pebbles of lead found with copper in a late cache at San Jose. The Nahuatl word for lead, which is *temetztl*, also implies an association with the moon (*metztli*).

There are two expressions for making fire. One, *hax kak*, is by friction. Since *hax* means to swirl something between the palms and the lower stick is called "the mother" (*u naa*) of the device (*artificio*), it is obvious that the apparatus, called *haxab kak*, was a fire drill. The other expression, *thah kak*, is the newer method with flint and steels

The Spaniards were somewhat slow in introducing iron, probably to keep the natives from possessing many metal weapons; and the rather ample vocabulary covering the processes of quarrying flint and shaping flint implements (ff. 7v, 134r, 150r, 159r; also Roys 1943:49–50) would seem to indicate that stone tools were still in use at the end of the sixteenth century.

Although many intrusive Spanish words are now to be found in the language, the old dictionaries show a remarkable ability on the part of the Maya to adapt their own language to the new animals, devices, and ideas introduced by the Spaniards. It is true that the crossbow was simply called *castelan chulul* ("Spanish bow"); but the musket was christened *dzon* ("blowgun"), and to shoot one was *dzon kak* (literally, "to shoot fire from a blowgun"). *Tzimin*, the former name of the tapir, was now applied to the horse, and in some localities today the tapir is called *tzimin kax* ("forest *tzimin*").

In both the Motul and Vienna dictionaries the vocabularies relating to the various crafts are very full. The items concerned with tanning include the words for scraping, cleaning, smoothing, softening, and dyeing the skins. The last operation was very important and the Maya equivalent of curtidor ("tanner") is sometimes given as *ah bon keuel*

("skin dyer"). Among the terms connected with the potters art are those for the special mortar used for grinding clay, the kiln, the materials for the slip, and various types of pottery including some reference to their decoration. I have been disappointed, however, in not finding any mention of the *kabal*, a block of wood which was set on the ground and rotated by the foot of the potter, somewhat like a potter's wheel. Spinning and weaving are well covered, including the materials employed, the parts of the loom, and the various kinds of cloth manufactured. The vocabularies of the other trades or professions are also ample, and the missionary who had studied these dictionaries diligently was well prepared to converse intelligently with almost every class of people.

One profession, however, which was of much interest to the missionary, could hardly be amicably discussed with its regular practitioners. This was sorcery. Besides medical incantations, which were a mixture of religion and magic, love spells, snake charming, and fortunetelling; there were two important branches of genuine black art. One was practiced by the *ah uaay*, who had a familiar animal spirit, usually a beast of prey. Like the European werewolf, he sometimes transformed himself into such an animal. The other was the *ah pul yah*, or "disease thrower," who might cause any affliction from a child's nightmare to a serious disease. As in the medical incantations, some magic was beneficent.

The vocabulary covering sorcerers and sorcery in the Vienna manuscript is much like that in the Motul, but it is by no means so ample. One supplements the other, however, and in the Vienna I find two interesting expressions, which I have not encountered elsewhere as magical terms. The word conjurar heads an item which reads: "To conjure the weather (los tiempos): *tzak kin*, *mac ik*." The first is hard to translate, but apparently it has something to do with the sun (*kin*). The other, *mac ik*, could mean "to obstruct or smother the wind."

Ixtla Weaving at Chiquilistlan, Jalisco

Isabel T. Kelly

At the time of the Spanish conquest, clothing of maguey fiber was common over a large area of western Jalisco and southern Nayarit. There are specific statements written in 1525 of its use in Tenamaxtlan, Ayutla, Autlan, Tequesquitlan (then in the Purificacion), Etzatlan, Ocotitlan, Aguacatlan, Ixtlan (del Rio), and in most of the settlements listed as subject to those just mentioned. For the first two pueblos and for one subject to Autlan, only maguey clothing is noted; the others are credited with both cotton and maguey. These data come from a 1525 visita, made the year following the entry of Francisco Cortez. The entire account appears to be systematic, conscientious, and reliable (Nuño de Guzmán 1937).

Today maguey fiber (*ixtle*) is used extensively in Mexico for rope and cordage, for scouring pads, mattresses, sweat blankets, floor mats, and bags and sacks of many kinds. When one reads of clothing of maguey fiber, therefore, one is inclined to think of a heavy, coarse, rough textile. This is not necessarily the case, as witnessed by the remarkably fine *ixtle* weaving still produced on a small scale in the little Jaliscan town of Chiquilistlan.

Chiquilistlan lies in the central part of the state, in the uplands north of Tapalpa, northwest of Sayula, southwest of Zacoalco, and southeast of Tecolotlan. It is not, as most published maps indicate, on the Rio Juanacatlan but on a small perennial stream which is said to drain to the Jalpa. I visited Chiquilistlan in the spring of 1941, in the course of an archaeological survey supported by a fellowship from the John Simon Guggenheim Memorial Foundation. At that

time Chiquilistlan was accessible by horseback from Tapalpa or from Tecolotlan, a trip requiring close to six hours from either point. However, during the past year, a new road has been opened to approach Tapalpa from the north; during the dry season this is traversed by trucks and is said to pass within a short distance of Chiquilistlan.

Concerning the etymology of Chiquilistlan, there are differences of opinion, with versions varying from Place of Crickets to Place Where One Cries Out and Scraped or Rased Place (Arreola 1935: 14; Paez Brochie 1940:22). Local residents have still a different interpretation, namely Place of the Weepers, saying that this refers to early and incessant appeals for more land. In Tapalpa the current and somewhat uncharitable translation is Place of Fleas or Place of Bedbugs.

During the middle sixteenth century Chiquilistlan was a part of the Provincia de Avalos, which centered in the Sayula drainage and included the western shores of Lake Chapala (*Papeles de Nueva Espana* 1905:1, no. 104, under Xequilistla). It is not certain, however, that cultural ties were with Sayula. A small collection of surface sherds, although not yet studied in detail, seems to suggest a local development, perhaps with ultimate ties to the north, with the modest culture of the Tecolotlan-Tenamaxtlan-Atengo area.

The history of Chiquilistlan is little known. Municipal archives were destroyed during the Cristero uprising; the church records may have escaped, but we were unable to arrange an audience with the priest, who was engaged in Holy Week ceremonies.

It is known, however, that in 1563, at the request of a local delegation, a formal title was issued and boundaries with adjoining pueblos were established. The title has been published (Cuadro 1881:4–9), and a copy of the pictorial map said to have accompanied the original title soon is to be published by Don Jose Ramirez Flores of Guadalajara.

Of subsequent history there is almost no record. The Chiquilistlan zone seems to have had a considerable if intermittent flurry as a mining center. Iron evidently was the mainstay of the town in 1843 (*Noticias geograficas* 1843:93); but gold, silver, copper, mercury, and lead also occur (Villasana 1916:150). Large-scale activities appear to have ceased before the middle of the nineteenth century (*Cuadro estadístico* 1881:13), but there must have been a subsequent renaissance. There is a statement to the effect that the quicksilver deposits were worked twenty-five years prior to 1905 by a company of Spaniards and Mexicans who employed state convicts as laborers (T. Smith 1903). Furthermore it is said that for five years prior to 1916 the mines of Chiquilistlan had been inactive (Villafana 1916:89).

A certain amount of activity and prosperity during the past century is attested by the surprising abundance of nineteenth-century English crockery in Chiquilistlan. This in itself presupposes a certain amount of outside contact. Furthermore, as far back as the early eighteenth century, the timber of the Tapalpa uplands was being exploited for sale in Guadalajara (Ornelas 1941:42). In other words, it cannot be assumed that Chiquilistlan had been genuinely isolated, even though it be relatively remote by modern standards.

Because of this, it seems curious that Chiauilistlan should be the seat of fine ixtle weaving, for the latter presumably represents the survival of an old, perhaps preconquest, craft. In 1881 the working of maguey fiber was listed as one of the local industries. It is said that “in this industrial branch the natives are very advanced, weaving mats and bags of maguey fiber which are so fine that they can be distinguished from muslin only because of their stiffness” (*Cuadro estadístico* 1881:13). Twenty years ago there were several weavers; today, the fine work is made by only one woman, Doña Sofia Gonzalez. There is, however, a large production of coarser ixtle goods.

Women purchase the fiber from the men who gather the leaves, for the latter are said to be harsh to handle. All fiber comes from wild plants (of several distinct kinds) which grow in the nearby hills. The supply has been greatly diminished, despite recent protection by the government forestry service. The cut leaves are placed on an inclined board and the flesh removed with a drawknife. For coarse work

the resultant fiber is spun; for fine textiles, each warp and weft is formed of *untwisted* fibers (Fig 42.1g, h). Fine weaving is done on a narrow loom, complete with heddles and batten, and attached to a waist strap. The warp strands consistently outnumber the weft, in one specimen six to one (Fig. 42.1f Random counts are given in the figure caption; warps range from 28 to 72 the centimeter, wefts from 12 to 24.

The fine work of recent years is confined to miniature bags and to table runners (Fig. 42.1a–g). Actually, the bags are of little practical utility but are prized as curiosities. Several still are treasured in Sayula, and a few in Chiquilistlan. Bag styles are well established. They include a simple, sack-like pouch (Fig. 42.1a–c), bags with an envelope-like flap (Fig. 42.1d, e), and miniature saddle bags, *arguenas* (Fig. 42.1f). Handles are of braided fiber and are sewn to the top, at either side seam. New specimens are a light cream; with age they turn straw-color. The fabric has a beautiful sheen and, except for the stiffness, might pass for raw silk.

A simple pattern usually is woven as border; it may be of dyed ixtle (Fig. 42.1a, b, d, e) or of woolen yarn (Fig. 42.1c, f); Figure 42.1 has a blanket-stitch edge of mercerized thread. The sacklike bags may have one selvage at the top, with the other edge hemmed; or both upper edges may be hemmed. The

42.1. Ixtle weaving at Chiquilistlan, Jalisco: (a–f) miniature bags, unspun maguey fiber; (g) table runner, unspun maguey fiber; (h) border of a shoulder bag of spun fiber. (a–c, f) made in Chiquilistlan, ca. 1923, for Sr. Cura Juan Quintero; gift of Doña Paula Quintero, Sayula; (d, e, g) made by Doña Sofia Gonzalez, Chiquilistlan, 1941; (h) purchased in Chiquilistlan, 1941, maker unknown. Below are the approximate dimensions of the bags, exclusive of handles, and of the exposed areas of the runner and larger bag. These measurements are followed by a random count per centimeter of the warp and weft; needless to say, the specimens are not mechanically uniform, and the count is somewhat variable.

		Warp	Weft
a	5 × 7 cm	32	23
b	12 × 16	28	22
c	10 × 11	29	19
d	13.5 × 15	44	22
e	15 × 16	68	23
f	6.5 × 7.5	72	12
g	17 × 11	50	24

V-flap of the envelope bags is hemmed with ixtle and ornamented with a simple-blanket stitch border, also in ixtle; some specimens have supplementary cross-stitch embroidery and drawn work (Fig. 42.1e).

Of coarser ixtle products, shoulder bags (*costalillos*) are most important and are made primarily for local consumption. They are simple, sacklike containers, wider than they are long; they are of spun maguey fiber, often with a simple woven border at the top (Fig. 42.1h). These bags are indispensable in every, rural household and are used chiefly for carrying food on the trail or to workers in the fields.

Other ixtle manufactures include a miscellany of items made for sale elsewhere. Their immediate destination is uncertain. Most people thought that the output was marketed in Guadalajara, although I have noticed no recognizable Chiquilistlan products offered there. The latter are sufficiently distinctive to attract attention, since they consist largely of filet crocheted bedspreads, table runners and mats, and bags, of fiber dyed in garish colors; magenta is predominant.

Even the relatively coarse shoulder bags of Chiquilistlan are considerably finer than is the average

work in other areas; some of the older specimens, in particular, are extremely fine and well woven. It might even be suggested that the Tapalpa upland as a whole has a tradition of good ixtle work. Grain sacks which ordinarily are attributed to Tapalpa, but which actually are made in nearby Atacco, are beautifully woven and are far better technically than are equivalent sacks from other zones.

I know only one other area in Jalisco where there is even a faint approximation to the fine weaving of Chiquilistlan. This is the small and impoverished settlement of Mazatan, on the Rio Armeria, downstream from Zapotitlan, and almost on the Colima border. Here the small shoulder bags enjoy local fame and are, indeed, extremely well woven, although they fall short of Chiquilistlan standards. I was not able to acquire a specimen of the fine Mazatan work but am under the impression that it also involves untwisted rather than spun fiber. In any case, I submit that if the aboriginal clothing of western Jalisco and southern Nayarit was of maguey fiber, we need not be supercilious. The natives may have been quite handsomely garbed if their weaving was on a par with that of modern Chiquilistlan.

SAN PEDRO TLAQUEPAQUE, JALISCO, MEXICO.

Worked Gourds from Jalisco

Isabel T. Kelly

So few crafts in modern Jalisco can be considered even potential survivals of pre-Cortesian arts that the working of gourds is of sufficient interest to warrant being placed on record.

Ayotitlan. The chief center of manufacture is the village of Ayotitlan, in the modern municipality of Autlan, not far from the Colima border. It lies in the rugged country (Fig. 43.1a) which drains to the Rio Sihuatlan (Marabasco) from the north and which, at the time of the Spanish conquest, constituted the western zone of the famous old Provincia de Amula. This whole area was better known in the sixteenth century than it is today, for modern routes of travel have left it to one side, and it is accessible only by pack or on foot.

Ayotitlan appears in the "Soma de visitas de pueblos" as Ayutla (Paso y Troncoso 1905:1, no. 168) and is said by local informants to mean 'place of gourds.' Another source (Arreola 1935:8) gives "lugar en donde cultivan calabazas." However, a 1579 account (*Noticias varias de Nueva Galicia* 1878:316) states that the name is derived from "calabasa" but was applied because a stone in the village was shaped like a calabash.

Gourd-working in this general area goes back at least as far as the early eighteenth century, for Ornelas (1941:43) speaks of "los tecomates que llaman de Acmulan." And a few decades later it is said that Ayotitlan is populated by seventy-six Indian families who make "Bateas, primorosamente pintadas" (Villaseñor 1746-1749:218). In former times the working

of gourds may have been general throughout the province; today it is limited to Ayotitlan and to nearby Telcruz, whose products are indistinguishable.

Ayotitlan considers itself an "Indian" community. A few of the elder residents still remember some words which clearly stem from Nahuatl; at the time of the conquest, Mexicano was understood generally throughout Amula, side by side with Otomi (*Noticias varias* 1878:315, 317).

Modern Ayotitlan is isolated, poor, and land-hungry. The village is situated on a low and sloping hilltop, in a cleft between higher hills, and with an abrupt mountain scarp to the north. It lies well above the level of the little Arroyo de Ayotitlan, which is tributary to the Sihuatlan. There is almost no level land; agriculture is virtually confined to hillsides, many of which are precipitous. The staple is maize, of which several kinds are grown; beans are planted separately but not in large quantity; and various cucurbits are raised. Other crops include tomatoes, tobacco, and chic (*Salvia hispanica* L., identification by the Instituto de Biología, Universidad Nacional de México). Along the arroyo there are a few small plots of sugar cane, and most houses have a cluster of banana trees adjacent. Fruit trees include guamuchil (*Pithecellobium* sp.), mango, guayabo, papayo, mamey, and aguacate; the growth is so rank that the village is almost hidden (Fig. 43.1a). Virgin pine (*ocote*) forests and oak parks cover the higher hills and adjacent sierra.

Few old-arts have survived in recognizable form. Until recent years, cotton was brought from the coast

Scenes at Ayotitlan: (a) panorama from the west, on the trail leading to Cuzalapa; village at lower right is all but hidden by vegetation; (b) Center of Ayotitlan; the house in the rear, with columns; faces the main plaza, which is partially hidden by adobe building in the middle ground; the shelter at the left serves as a church; (c, d) village inhabitants; (e) woman spinning.

at Sihuatlán, and was spun and woven locally. At least one woman still spins (Fig. 43.1e), using a slender rod and a baked clay whorl. But she makes only cordage for lamp wicks, and cotton weaving seems to have been entirely abandoned. Yucca (*izote*) fiber also is worked into cordage, being twisted between the palms or on the thigh. It is woven into shoulder bags (*costalillos*) which, from description, appear to be made on a belt loom. Hammocks of yucca fiber, used chiefly as cradles, are said to be warped on a frame of two upright posts. Baskets are made of cane (*otate*) splints but not in sufficient quantity to meet local demand during harvest season. The manufacture of *equipales* may be old; these seem to be mostly low stools, but it is said that chairs also are made. The seat is woven of the bark of an unidentified tree (*cuernavaca*); cane (*otate*) is used for the diagonal seat supports. A few women make crude, undecorated, and unglazed cooking pots for home use, and several exhibited metates, likewise of their own manufacture. These grinding stones are footless and might easily be confused with archaeological specimens.

By far the most interesting of the local crafts is the preparing of gourds; they are the only manufacture which Ayotitlán supplies to outside commerce. Formerly they were sold in Manzanillo (Colima), Pueblo Nuevo (old Cuautitlán), Autlán, Tuxcacuesco, and Sayula (all in Jalisco). The bulk of the output was prepared for sale at the annual Holy Week fair (El Ramos, in local parlance) in Sayula, but in recent years the supply has been largely absorbed by traders who come on foot from Zamora, Michoacán, to carry back shoulder crates filled with Ayotitlán gourds. The traders often pass through Sayula at the time of the fair but prefer not to sell locally, since they obtain a better price in Michoacán.

I visited Ayotitlán at Christmas, 1940, in the course of a survey supported by a grant from the John Simon Guggenheim Memorial Foundation. At this time the gourd harvest was barely ripe and had not yet been worked. No plants were available for identification, and I assumed that the common gourd (*Lagenaria vulgaris* Ser.; Martínez 1928, under *Bule*) was involved. A Tuxcacuesco informant, however, believes that there are two more or less distinct plants, both with white blossom, both called *m to de bule*, but one producing the bottleneck form, the other, fruits which are less elongated and more nearly round.

Few worked specimens were available for demonstration, but informants gave a brief account of the preparation, which is summarized below, together with supplementary data from informants in Tuxcacuesco and Sayula.

At the start of the rainy season (May–June) seeds are planted in the hills of the arriera ant; it is said that elsewhere the ground is hard and the young plants dry. From time to time the fruit is tapped to determine the degrees of ripeness. Finally, during December, it is cut from the vine and piled until the women have time to prepare the gourds. Many are said to understand the technique; an inexperienced worker generally has a heavy breakage.

Gourds are cut to form several standard shapes (see below), and the seeds and pulp are removed. If desired, simple geometric designs (Fig. 43.2b–e, g, h; Fig. 43.2f unique in its floral motif) are marked with a steel awl, set in a wooden handle. Some of the older specimens, purchased several decades ago at the Sayula fair, show more precise delineation of motif and some evidently were marked with a hot iron (Fig. 43.2e, g, h). The incised gourd is placed in water for twenty days then is allowed to dry for eight days, after which the interior is cleaned with a small stone and is rubbed smooth.

Next comes the interior finish, for which chic oil and red earth are used. Chia is a cultivated crop, sown broadcast in separate fields. It ripens at the end of December, and its seeds are ground to extract the oil (the entire, unground seed is used to make a beverage). The gourd interior is saturated with the oil; red earth dug from nearby hills is worked in, being well polished with a *coquito* palm nut brought from the coast at Sihuatlán; a pebble is said to be too heavy. Then comes a second dressing of oil, rubbed in with a tuft of cotton. Several applications of red earth follow (none of oil), until the entire interior and the rim of the exterior are smooth, hard, and polished. The finish is terra cotta in color, often with faint purplish cast. It is surprisingly durable and water-resistant. Figure 43.2c, f shows two specimens which have been in daily use for nearly ten years; the interiors are somewhat worn but largely intact.

Ayotitlán gourds have many uses. The large *jicaras* (Fig. 43.2a) are almost traylike and are used for serving and storing food. Smaller ones (Fig. 43.2b, c) function as dippers for removing water from household storage deposits. Incurved bowls, of relatively wide mouth, are known as *tecomates* (Fig. 43.2d, e); they also are used as dippers and as general kitchen containers. Incurved bowls with restricted orifice are called *balsas* (Fig. 43.2f, i). Large ones are the standard receptacles for tortillas, as the latter are removed from the fire; the small opening helps to keep the maize cakes warm and tender. Balsas also are used for general storage; the Ayotitlán spinner (Fig. 43.1e) keeps unspun cotton in one. Perforated at the rim for suspension or for carrying, they serve

43.2. Gourds: (a–d, f) Ayotitlan gourds; (a, f) gifts, Tuxcacuesco, dating from 1934; (b–d) purchased, El Ramos, Sayula, 1941, from Ayotitlan vendors; (e, g–i) “old specimens,” purchased “many years ago,” El Ramos, Sayula; (e, g, h) almost surely from Ayotitlan (*i* possibly). (a–h) incised ornament; (e, g, h) marked with hot iron; (a) special order, inscribed with date and name of Tuxcacuesco purchaser; (f) unique in its floral motif; (i) decorated in stripped painting; not to uniform scale; approximate rim diameters of a–f, *i*, respectively: 41, 27, 25, 18, 10.5, 17, and 7.8 cm. Lengths: (g) 28.3 cm; (h) 21.5 cm.

as pulque containers. Small balsas are used for storing miscellanea.

Two forms were not mentioned by Ayotitlan informants. One is a large spoon or ladle (Fig. 43.2g, h) produced by cutting a bottle gourd lengthwise instead of transversely. In Sayula such ladles formerly were used for serving maize gruel (*atole*); in recent years their manufacture seems to have been abandoned. The other form is the *alacate*, a long, tube-like gourd, used for sucking the juice from pulque maguey. It is said that formerly alacates from Ayotitlan were sold in Sayula and that some were decorated. Obviously, because of the form, the interior could not have been treated with oil and red earth.

The use of chia oil is of particular interest because, according to sixteenth-century reports (Paso y Troncoso, 1905, 5:180, 6:319) this same oil was used in Guerrero (presumably in the working of gourds). Traditionally, it is the oil which, together with that of the chicalote (*Argemone* sp.), was used in the preparation of Uruapan "lacquers" until it was replaced by commercial linseed (León 1921:333, 336). Moreover, I am informed by Ins. Roberto Weitlaner that chia oil is used in the preparation of gourds at Acapulahuaya, Guerrero. He reports that the seeds are toasted, ground, and the oil squeezed out with the hand. The technique at Ayotitlan probably identical, although informants did not mention toasting the seeds, and I did not think to make specific inquiry. In any case, the use of this oil is a most suggestive parallel between the gourd-working of southwestern Jalisco and that of Michoacan and Guerrero. At Ayotitlan and Acapulahuaya its current use may well represent the survival of an old culture trait, formerly more widespread.

Sayula. Sayula is a relatively large (ca. 9,000) Jaliscan town, too well known to require any introductory statements concerning location or terrain. Here, during at least the second half of the past century, elaborately ornamented gourds were produced (Fig. 43.3a–c). They seem not to have been turned out on a large scale but were made during spare time, as curiosities rather than commercial products. Various individuals reputedly decorated gourds, and craftsmen ranged from prisoners in the local jail to the church notary.

I have seen five gourds from Sayula. One is in the Museo Regional at Patzcuaro, Michoacan; one (Fig. 43.3a) is the property of the Brooklyn Museum; two (Fig. 43.3b, c) are in my possession; and one is or was in the hands of a Guadalajara curiosity dealer. All these Sayula specimens are balsas and presumably were pulque containers.

Sayula informants give contradictory statements concerning the manufacture. Some are under the impression that the product was entirely local, from the terra-cotta lining to the incised ornament. Others believe that Ayotitlan gourds, already prepared on the interior, were purchased at the Easter fair, and that subsequently they were decorated in Sayula. The latter seems highly probable, for at least three (Fig. 43.3a, 1) of the five Sayula specimens bear the typical, extremely simple Ayotitlan geometric motifs at the rim. But below this border are the involved realistic and conventionalized designs which characterize the more sophisticated Sayula work. The latter ornament presumably was copied from commercial patterns, perhaps embroidery books. Motifs include arabesques, the national eagle with the serpent in his beak, sprays of flowers, and so on. One specimen (Fig. 43.3c) is less stereotyped and is covered with an involved assemblage of animal, human, and floral motifs. There are scorpions, fighting cocks, birds, a fish, a dog, a goat, a crab, an armadillo, and several unidentified animals. Human figures include three women with long, full skirts; a man on horseback; another in Indian costume, armed with bow and arrow. With this latter exception, the men wear formal attire: a tall hat, a long full coat, and tight-fitting trousers.

The Sayula specimens are inscribed. That in the Patzcuaro Museum says, "Miguel Ponce, gravada en Sayula, setiembre de 1865." Another (Fig. 43.3a) is dated 1872. Still another (Fig. 43.3b) is marked "Teofilo Davalos Sayula Julio 5 de 1882." That shown in Figure 43.3c is undated but states, "Sirbo a mi dueño Alejandro Dias."

It is said that even now, pulque vendors in Sayula buy simple Ayotitlan gourds and add incised ornament to their liking. One balsa which perhaps belongs in this category is marked "Sayula Marzo 30 de 1910"; on the opposite side, but painted, is the name "J. Ines Covarrubias." The incised border of this specimen is simple and is less tidily executed than is the run of Ayotitlan work.

In all probability the worked gourds of Sayula may safely be regarded as a mid- and late nineteenth-century offshoot of the Ayotitlan craft. During those decades, carving and incision seem to have had a considerable vogue in Sayula. Jewelry (necklaces, bracelets, brooches) were carved, as were horns for calling cattle; and short lengths of cane were incised and used to hold rolled papers or letters (Fig. 43.3e). The illustrated cane bears several motifs virtually identical with those of Figure 43.3c, and it seems not unlikely that both were incised by the same unidentified individual.

Except for occasional products of pulque vendors, decorated gourds of the types described above

43.3. Incised objects from Sayula: (a–c, e) nineteenth century; (a–c) gourds; (e) cane tube; (d) modern; tree gourd; various scales. Rim diameters: (a) 7 cm; (b) 7.8 cm; (c) 9 cm; max. width of *d*, 9.5 cm; length of *e*, 20.5 cm.

no longer are made in Sayula. Today the fruit of the tree gourd (*cuastecomate*, presumably *Parmentiera elata* Pliers; Martinez, 1937:128; Arreola 1935:9) is stained and incised for tourist consumption. Motifs on the illustrated specimen (Fig. 43.3d) include an Indian head, a dove bearing a letter, a swan, and twin volcanoes. These tree gourds are not cut or hollowed to form receptacles. They are left entire, and a small quantity of mezcal liquor and a piece of stick cinnamon are introduced through a break made at the stem juncture. The concoction is allowed to ferment the pulp, and the resultant product allegedly is medicinal, being recommended especially for pulmonary disorders. Tree gourds are similarly decorated in nearby Ciudad Guzman and perhaps elsewhere.

San Pedro Tlaquepaque. This is a small town adjacent to Guadalajara. Its gourd industry is so unobtrusive that, after three years of nearly continuous residence there, I was completely unaware of any such enterprise. Quite by chance my aide, Jose Maria Corona, noticed through an open doorway that a number of gourds were being packed; he made inquiry and determined that they had been prepared locally.

Tlaquepaque gourds are unornamented except for the usual terra-cotta lining. The interior is scraped clean with an iron tool which is roughly stirrup-shaped but with the arc not completely closed; one or both (?) edges of the curve are sharpened. The lining is produced by applications of raw linseed oil and red earth, the latter purchased in nearby San Martin de las Flores. A small stone (*piedra china*) is used for polishing, and the final sheen is said by one informant to be applied by burnishing with the leaf of an orange tree. There is no knowledge of chia oil.

Raw gourds are purchased for the most part in San Martin. Formerly, the Hacienda de Oblatos, a few kilometers north of Tlaquepaque, supplied a considerable quantity. Present workers include Doña Concepcion Corona and two brothers, Don Fausto and Don Raymundo Tornero. The first-mentioned and one of the Tornero brothers were interrogated but could give no information concerning the age of the local industry. Both learned from relatives of the past generation, now dead. Other informants, not gourd-workers, were similarly vague. But some thirty or forty years ago there must have been close to a dozen persons who devoted at least a portion of their time to preparing gourds.

The process presumably was secret, and individuals worked at night so that the technique would not be witnessed. It is said that formerly Tlaquepaque specimens were decorated, but no example could be found, nor could a coherent description of the

ornament be obtained. It appears almost certainly to have been incised.

Tlaquepaque gourds are prepared exclusively for sale elsewhere; this appears to have been true in times past as well as present. The bulk of the lot is taken to the annual fairs in San Juan de los Lagos and in Sayula. Any excess finds a ready market in Zamora, at a good price. In the course of nearly five years of residence in the Guadalajara area, I have never seen a lined gourd for sale in the local markets, either in Guadalajara or in Tlaquepaque.

It is not impossible that the local work, like that of Sayula, stems from Ayotitlan. Traditionally, large quantities of Tlaquepaque and Tonalá pottery are taken to Sayula for sale at El Ramos (in local parlance), the same fair which, in former times, was the chief outlet for Ayotitlan gourds. Thus residents of Tlaquepaque had at least first-hand contact with vendors of the Ayotitlan products. Today the craft is spreading from Tlaquepaque, and within the last few years several persons in San Martin are said to have imitated the Tlaquepaque technique of preparing gourds.

Unplaced. The specimen shown in Figure 43.2i, is of unknown provenance, as is a large jicara decorated in similar technique and on display in the Patzcuaro Museum. These two examples are of some interest since they are ornamented in what may be called stripped painting. The interior is finished with the usual terra-cotta lining, but a similar coating of pigment has been applied to the exterior, then cut away to expose the gourd surface and to delineate rather involved designs. The illustrated specimen bears an elaborate floral and butterfly (?) design. It is the gift of Doña Paula Quintero, of Sayula. The donor, who claims to be well over eighty years of age, says that this gourd was purchased at El Ramos, in Sayula, by a much older half-sister. No precise date can be assigned, but the chances are that the specimen is at least sixty or seventy years old.

Friends in Tuxcacuesco and Sayula do not remember having seen Ayotitlan gourds with this type of ornament. Unfortunately, this particular example did not come to light until after my visit to Ayotitlan, hence no inquiry was made there. Nevertheless, my guess would be that these examples of stripped painting may represent an old Ayotitlan decorative treatment which was abandoned years ago.

Stripped painting parallels a decorative treatment which occurs archaeologically in western Mexico and elsewhere in the republic. The archaeological examples involve pottery rather than gourds, and two or more colors. But technically, the treatment is closely parallel. In each case, large, zones of

unfired pigment were applied to the surface of a vessel, then cut away to expose the underlying ground. This is, of course, the basic principle of the modern Olinala (Guerrero) "lacquers," the more complicated specimens of which involve several layers of pigment of various colors. Archaeological occurrences of stripped painting come from Chanchopa, near Tecoman, Colima (in definite Teotihuacan III association); from Apatzingan, Michoacan (unplaced chronologically); from Los Volantines, Tzintzuntzan, Michoacan (unplaced but Preclassic Tarascan); and from Monte Alban (in Monte Alban II association). Evidently the stripped technique is of considerable antiquity and of considerable distribution. Its appearance on what, presumably are two nineteenth-century gourds from Jalisco is, consequently, of historic interest.

In summary, it may be said that the rather modest worked gourds of modern Jalisco probably rep-

resent a survival of an old and formerly widespread culture trait. The Ayotitlan occurrence may be the survival either of a simple, archaic style or of an attenuated, peripheral manifestation, marginal to a Michoacan-Guerrero center. In the latter zones and at Ayotitlan the use of chia oil is a precise and probably significant parallel. The nineteenth-century ornamentation of gourds at Sayula probably is little more than a Victorian gilding of the Ayotitlan lily. Nothing is known of the history of the modern Tlaquepaque gourds, which are undecorated except for the terra-cotta lining; they may represent a distinct survival or they also may be offshoots from the Ayotitlan center.

Two gourds ornamented in stripped painting are of unknown provenance. Technically, their ornament is closely related to the stripped painting which occurs archaeologically in western Mexico and in Oaxaca.

SAN PEDRO TLAQUEPAQUE, JALISCO, MEXICO

The Graphic Style of the Tlalhuica

R. H. Barlow

One of the means by which the boundaries of pre-hispanic Mexican cultures may be traced is by mapping the codical and petroglyphic styles of different zones. Connections between these areas and linguistic or ethnic groups will then often become clear.

It is true that we now know with certainty that the Nuttall and Vindobonensis group come from such towns as Tilantongo and Teozacualco in Oaxaca, as Caso has established on the basis of the unpublished codex of the latter town. This same style of painting obtained as far west as Tecomaixtlahuacan (Schmieder 1930, Appendix I), and other frontiers can doubtless be defined. A second distinctive style, that of the Borgia group, has been linked to the Tlaxcala area via the altars of Tizatlan. But a number of art styles remain to be defined geographically (the Huamantla style, for example) and the graphic traditions of Morelos have never been examined.

A good specimen of the style I shall call Tlalhuica, for reasons advanced below, is afforded by the Codex of Xochitepec, Morelos, a tracing of which was generously loaned the writer by Sr. Guillermo Echaniz (Fig. 44.2). This codex was seen and traced by Francisco del Paso y Troncoso, and the tracing exhibited in Madrid in 1892, though it does not appear in the published catalogue of that exhibition. Later the tracing came into the hands of Sr. Ramon Mena, who wrote a one-page explanation identifying it as coming from Xochitepec, Morelos. It was purchased from him by Sr. Echaniz. Where the original is, does not seem to be known.

The chief purpose of the present note is to make the codex available as a touchstone for the Tlalhuica art style. A summary comment on the subject matter of the codex, however, will not come amiss.

The tracing measures 80 by 88 cm. It has been colored by hand with a cream background suggesting native paper, which agrees with Sr. Mena's note, and a few details are painted in weak greens, browns, pinks, and grays. It is obviously a colonial production but one which follows native styles, and it deals with matters of genealogy, tribute, and landowning.

Left Hand of the Codex. Down the left margin six chiefs sit on mat "thrones," all with closed eyes denoting that they are dead. In the center of the codex a vertical column of ten other figures faces them, only the bottom one being painted with an open (living) eye. This personage is clearly the descendant of so many generations, the last figure in a 300-year stretch, if we assume the conventional number of thirty years to a generation. On this basis the first figure in the central column would be the founder of the dynasty in Chichimec times, around A.D. 1200. It will be noted that the areas of matting are drawn as if to represent a great variety of weaves.

Between these two columns of dignitaries are six human heads, two of them female, as the coiffure indicates, and eight turkey heads accompanied by an equal number of what appear to be eggs. Each egg in turn bears the fern-shaped symbol for 400. In the top row in front of the female heads are two rolls of paper tied about (Fig. 44.1i) and a sharp-pointed

tepetl glyph; and in the second row, immediately below the latter, a house decorated with checkerboard painting.

In the left central part of the codex, below the turkey heads, six squares, one of them having two divisions, denote six milpas. As these do not have the glyphs of their proprietors painted inside them, it is possible that their ownership was under discussion, giving occasion to the painting of the codex. In the lower left-hand corner a person of authority in a Spanish hat sits on a Spanish chair above another *tepetl* sign, toward which two streams flow from two smaller plots of land. These two small plots seem to be property of the two masculine heads drawn close to them, heads which are accompanied by a symbol resembling a drum, the meaning of which the writer does not know.

Right Hand of the Codex. The other side of the *mapa* is divided into numerous small plots of land, which with one or two exceptions bear the glyphs of their owners, sometimes for two generations. In seventeen cases the owners are women, as the style of hairdressing in two knots on the forehead indicated (Fig. 44.1b, c). Many of these women have names which include the element "Xochitl," represented by a conventionalized flower. One man wears a noseplug; another, a beard. Footsteps, indicating paths, follow the margins of the fields and divide them into two mayor areas.

Parallels. Other manuscripts in the same style are known from the Cuernavaca area and from Tlaquiltenango. The Cuernavaca manuscripts, originating in various barrios of that center, such as Caltengo, and in such nearby towns as Xiuhteppec, deal also with landholding. (They are twenty-eight in number and are published in *Códices indígenas de algunos pueblos del Marquesado del Valle de Oaxaca* (1933). These Cuernavaca *mapas* provide us with additional glyphs, the glyph of Xochitepec itself (Fig. 44.1m) and what appears to represent the new crop, sugar cane (Fig. 44.1j).

Most of the abundant Tlaquiltenango collection reposes unpublished in New York (*Tlalocan*, 1:4), but the fragments called the Codice Mauricio de la Arena and published by Mazar (1926) suffice to indicate that the Xochitepec-Cuernavaca tradition prevailed in that town also. Moreover, Codex

44.1. The Tlalhuica style of painting: (a, b, f) Codex of Xochitepec; (c) Mauricio de la Arena (Tlaquiltenango; copied from original); (d) glyph from Mauricio de la Arena (Tlaquiltenango); (e) glyph from Algunos codices, cod. 3; (g) Algunos codices, cod. 28 (from Tlaquiltenango); (h) Algunos codices, cod. 11 (from Caltengo; cf. cod. 1); (i) glyph for paper, Codex of Xochitepec; (j) glyph for sugarcane, Algunos codices, *passim*; (k, l) glyphs for Xochitepec and paper, for comparison, Matricula de Tributos; (m) glyph for Xochitepec, Algunos codices, cod. 10 (Caltengo); (n) sketch map of area.

28 of the "Algunos codices" volume was painted in Tlaquiltenango.

I have called the style of painting dealt with in this note Tlalhuica. This would appear to be a safe denomination, since the three towns mentioned fall within

44.2. Codex of Xochitepec.

the Tlalhuica zone, and the paintings are in a style which still flourished in the mid-sixteenth century. The relief decoration of Xochicalco and Jonacatepec (Guzman 1934) and other points falling in the same area is probably pre-Tlalhuica, part of a southern art style containing strong parallels with Monte Alban III and the altars at La Venta. They presumably represent the art style which flourished before the arrival

from the north of the Tlalhuica with their distinctive Cuernavaca-Xochitepec-Tlaquiltenango style.

A map (Fig. 44.1n) of the zone demonstrably occupied by the Tlalhuica tribe, based on my paper on the geography of Moctezuma's empire (1949), is included. By means of the Morelos codices listed in Mazari's (1926) a more exact definition and delimitation of the Tlalhuica art style should be possible.

Variant Methods of Date Recordings in the Jatate Drainage, Chiapas

J. Eric S. Thompson

In most Maya inscriptions which include several Secondary Series, reckonings are made by additions to or subtractions from the last recorded date. Thus, if A is the Initial Series and B, C, and D are Calendar Round dates, an inscription will usually run: A $\pm$ 1st D.N. = B; B $\pm$ 2nd D.N. = C; C $\pm$ 3rd D.N. = D. Here D.N. stands for distance number.

In the only two lengthy and fairly legible inscriptions now known from the Jatate drainage of eastern Chiapas a somewhat different arrangement is followed. The distance numbers are not cumulative, that is to say, not reckoned from the last date reached, but give the total interval between the Initial Series and the recorded date. The arrangement is: A + 1st D.N. = B; A + 2nd D.N. = C; A $\pm$ 3rd D.N. = D.

Such a system is to be found on Stela 3, Santa Elena Poco Uinik, the various dates of which have been deciphered by Blom (Palacios 1926:138; Palacios and Meyer 1932:52), and Thompson (Note 7). The decipherments can be found in the table at right.

It will be noted that of the five distance numbers, four relate the associated Calendar Round date with the Initial Series, but the latter is not repeated. One distance number is of the normal cumulative type. Attention has been called by Thompson in the paper cited to the various examples of Glyphs G and F of the Lunar Series placed between the two parts of three of the Calendar Round dates.

Monument T-20, Tonina, was discovered by Blom and La Farge (1926-1927:289-92). Blom reads the Initial Series, most of which is on a missing fragment, as 9.18.0.0.0 11 Ahau 18 Mac. His reading is

Books: En Los Confines - Palacios 1926, page 111

A1-A8	9.18.0.0.0	11 Ahau 18 Mac
C8		Count of the tun completed
A10-A11	1.4.7.14	Anterior date indicator
B11-B12	9.16.15.10.16	2 Cib 14 Ceh. Glyph G9. Glyph F?
	(9.18.0.0.0	11 Ahau 18 Mac) not repeated
C12-A13	8.7.2	
C15-B16	9.17.11.10.18	5 Eznab 16 Mol? Glyph G2
	(9.18.0.0.0	11 Ahau 18 Mac) not repeated
C16-B17	8.3.4	Anterior date indicator?
C17-C18	9.17.11.14.16	5 Cib 14 Ceh. Glyphs G8, F
C20-B21	7.17.0	Posterior date indicator
C21-A22	9.17.19.13.16	5 Cib 14 Chen
C22	4.4	
	(9.18.0.0.0	11 Ahau 18 Mac)

amply confirmed by the new readings now presented. In order to retain the Blom lettering, the top column will be given the reference letters Upper C-D. The photographs of this stela in the work just cited are on the whole superior to my photograph (Fig. 44.1a), but the latter is reproduced because it shows certain details more clearly than does the former.

Columns A and B are badly damaged. They record in part a Lunar Series with a possible 5E (A2), Glyph C probably without a coefficient and with a fish-head count prefix (B2), Glyph B with same prefix to left (B3), and Glyph A with coefficient which is

probably 10 (A4). There follows an indecipherable reckoning.

Columns C and D have two Calendar Round dates and two distance numbers: The whole can be restored without serious question as:

Upper C-D1-B1	9.18.0.0.0	11 Ahau 18 Mac
C1-D2	1.14.13.11	With S.S. Introductory Glyph
C3-C4	9.16.5.4.0	6 Muluc 17 Mol. Glyph G8?
D4		Lunar computation indicator
	(9.18.0.0.0	11 Ahau 18 Mac) not repeated
C6-D6	1.4.11	
C7-D7	9.17.18.13.9	2 Muluc 12 Chen

The first Muluc is badly eroded, but the details of the second are reasonably clear on a photograph taken this year (Fig. 441a). The first distance number is quite straightforward, and 1.4.11 is the best reading for the second on inspection alone. Mol is quite clear, and its coefficient is best as 17 with 19 the only alternative. The second month sign has a clear coefficient of 12, and appears to belong to the Cauac group. The Cauac infix on the right is fairly clear, and the superfix resembles closely one of the variants found with Chen.

There appears to be another Secondary Series at the top of Columns E and F but the details are not clear, and no associated Calendar Round date is recognizable. Perhaps 11 Ahau 18 Mac, a repetition of the Initial Series date, occurs at E4-F4, but as there is some doubt as to the month sign and its coefficient, this is far from certain. Furthermore, there may be another Secondary Series at E8 and perhaps on the missing F8. At least we can be certain that two of the Calendar Round dates are reckoned directly from the Initial Series.

Two more cases of the occurrence of Glyph G with Calendar Round dates at Tonina may be noted.

Monument T-17 is a rectangular stone block first illustrated by Blom (Fig. 44.1b-d). The last glyph on Side A records 3 Ahau. The three glyphs on Side B read: Glyph G9, Glyph F, 3 Xul. An examination of the original revealed the features of the head for Xul quite clearly. The second glyph on Side C is probably the tun-count-completed glyph. There can be no question that the whole reads:

(9.12.5.0.0)	3 Ahau 3 Xul	Glyph G9, tun count completed
--------------	--------------	-------------------------------

Monument T-1 now supports a post of the veranda of the kitchen of the house in front of which it was found by Blom and La Farge.

Glyph B1 is Ahau with a coefficient which is best as 12. A2 is partially missing, but enough remains to make it virtually certain that it is Glyph G9. B2 is the month sign with coefficient of 18 to left. The main element is a head with the prefix to left. Prefix looks like that of Yaxkin and Yax. C2 is tuns. The crescentic form of the suffix shows that this is to be read as a distance number. E1 has a coefficient of 9. Blom reads the glyph as Ahau. D2 is a very clear 18 Xul. E2 is the tuns-lacking glyph. Morley has already placed the second date at 9.15.15.0.0.

The whole inscription, accordingly, reads:

B1-B2A1-A8	(9.15.11.0.0)	12 Ahau 18 Yaxkin? G9
C2	4 (0.0)	
E1-E2	(9.15.15.0.0)	9 Ahau 18 Xul. Five tuns lacking.

Tonina supplies yet another example of the interposition of Glyph G between day and month of a Calendar Round date. This is to be found on Monument 30, Tonina, first illustrated by Seler (1901, Fig. 282) and reproduced by Blom and La Farge, (1926-1927, Fig. 256). Unfortunately the date can not be read. The first three glyphs record respectively: day sign with coefficient of 12, Glyph G2, and what is presumably a month sign with a coefficient of 2 or perhaps 3 or 4. Glyph G2 is clearer than any other part of the text.

A small rectangular stone with glyphs lies close to Structure A, Tonina. This appears to have been seen first by Heinrich Berlin. It was given the number 42 by Money and myself in the spring of 1944. There is no Calendar Round date on the surviving fragments, but two juxtaposed glyphs record Glyph G9 and what may be count of a katun. The former is unmistakable. It is the head of the aged sun god with kin headdress surmounted by three shells, and with sweeping "tail" element to the right (Fig. 44.1e).

A single stela was found at Tzendales, on the river of that name, by A. M. Tozzer. The Tzendales River is an affluent of the Rio Lacantun, into which it flows a short distance above the confluence of the Jatate with the latter. The site, therefore, is in the neighboring drainage. The stela carries a short inscription drawn and deciphered by Spinden (1913:197; 1924:272). The opening date is (9.12.19.1.1) 7 Imix 14 Zip. This is connected with 9.13.0.0.0 8 Ahau 8 Uo at the bottom of the column by a distance number of 16.19. Its position in the Long Count is therefore certain. There is a glyph between 7 Imix and 14 Zip which, as drawn by Spinden, is almost certainly G3 combined with Glyph F. The latter is quite plain. Of

45.1. Inscriptions at Tonina: (a) Columns B–F, Monument T-20; (b–d) Monument T-17; (e) Monument T-42.

the former, Spinden's drawing, made hastily, shows details strongly indicating the two compartments of G3 and the encircling dots. It must be remembered that at the time this drawing was made, the meaning of Glyph G was unknown, and that consequently there can be no question of reading into the glyph block the details one would like to see. The Calendar Round date calls for Glyph G3.

There are now at Tonina one dubious and six certain examples of Glyph G unassociated with Initial Series, four examples of the same arrangement on Stela 3, Santa Elena Poco Uinik, one on the ball-court marker at Chinkultic (Señor Javier Mandujano Solorzano, of Comitán, informs me that this marker was actually found by his father, not at Chinkultic but at Colonia La Esperanza, about 9 km farther north), and one almost certain example at

Tzendales. In three cases Glyph G is accompanied by Glyph F. The idea may have traveled up the Rio Lacantun since it also appears at Yaxchilan (Lintels 3 and 10), and perhaps on Stone 2 of the Hieroglyphic Stairway at La Amelia (between 13 Manik and 15 Tzec).

Accordingly, in the marked tendencies to connect Calendar Round dates directly with the Initial Series and to associate Glyph G and sometimes Glyph F with Calendar Round dates, these rather peripheral Maya sites diverged somewhat from standard Maya practice. The differences, however, were in the nature of emphasis on known methods rather than in the development of new methods.

It is tempting to associate these variations with linguistic divisions. All three sites are in Tzeltal or Tojolabal territory.

The Venus Calendar of the Aztec

R.C.E. Long

Sahagun says that the Aztec festival of Atamalqualiztli occurred every eight years, sometimes in the month of Tepeilhuitl and sometimes in the month of Quecholli, and that after seven days of fasting the principal ceremony took place on the eighth day. Nothing is said as to when these festivals fell, so they cannot be fixed in the calendar, nor is there any indication of the days of the month or of the tonalpoualli on which they fell. The statement that they were sometimes in one month and sometimes in another is not made about any other festival. The commentator of the Codex Telleriano-Remensis says that Atamalqualiztli was celebrated in Tecpatl years, each of which necessarily had different numbers, and that it occurred or rather should have occurred in 1548, which was a year 4 Tecpatl. Using the table of Dr. Alfonso Caso and allowing for the shift in the vague year, one can show that in 1548 Tepeilhuitl began on 9 Quiahuitl 1 Tepeilhuitl, 4 October 1548 Julian, and that Quecholli ended on 9 Tecpatl 20 Quecholli, 12 November 1548. So the festival fell somewhere between these limits.

According to Sahagun, Motolinia, and other Spanish sources, the "Indians of New Spain" worshipped the planet Venus and knew when it would appear again in the east (heliacal rising). An Indian was sacrificed at dawn on that day as soon as the star became visible. Seler has shown that in the Codices Vaticanus B, Fejervary-Mayer, and Borgia, all of which are from south-central Mexico, and perhaps of Mixtec or Cholultec origin, many pages relate to Venus, and that the days Cipactli, Coatli, Atl, Acatl,

and Ollin which occur on these pages are the ending days of synodic periods of Venus of 584 days each. But he properly adds that in none of these codices is there a detailed statement of the Venus calendar such as that in the Dresden Codex. So in these supposedly Mixtec picture writings we can only infer the existence of a Venus calendar from the repetition of the days appropriate to it. As far as I know there is no Aztec codex showing these days and no Spanish source specifying on what dates either the Aztec or Mixtec celebrated their Venus festivals.

Several years ago it occurred to me that the Atamalqualiztli festival might be connected with Venus, owing to its occurring every eight years, but there was no evidence available in support of this theory. Now, however, Mrs. Makemson (1943) has greatly advanced our knowledge of Maya astronomy and, what is important for the present discussion, has fixed the position of the Dresden Codex Venus tables in the Long Count and in the Julian calendar. Carrying forward the Maya Venus computation to the sixteenth century, she shows that 11.14.13.7.0 1 Ahau 18 Pop fell on 12 August 1513 in the Julian calendar and was by Maya calculation the date of a heliacal rising of Venus; and, what is very remarkable, that the true date of heliacal rising according to Willson's tables was only three days earlier. We have then the following:

Maya Venus calendar end	11.14.13.7.0	1 Ahau 18 Pop, 12 August 1513
Add 4 × 8 vague years	1.12.8.0	

Reach	11.16.5.15.0	7 Ahau 18 Pop, 4 August 1545
Add two synodic periods	3.4.8	
Reach	11.16.9.1.8	5 Lamat 11 Tzec

But this would be 7 Itzqintli 12 Tepeilhuit for calculated heliacal rising in 1548 and the true rising was probably about 11 October, that is, 3 Miquiztli 8 Tepeilhuitl. It was usual for Aztec feasts to fall at the end of the period named from them, so probably the feast of Atamalqualiztli fell on 2 Tecpatl 20 Tepeilhuitl as the eight days began to run from heliacal rising, or on 11 Ocelotl 16 Tepeilhuitl, 19 October 1548 if counted from true rising.

From the above calculation we see that Atamalqualiztli may have fallen eight days after heliacal rising, calculated or observed, but that it did not fall eight days after the end of one of the eight-year periods of the Maya Venus calendar. Of course there is no reason why it should. It must occur near heliacal rising to agree with the astronomical facts but need not be at a date fixed by the Maya formal reckoning. The Aztec Venus calendar, like their annual calendar, was no doubt quite independent of the Maya one, and we know that the Aztec (or at any rate the painters of the Borgia group of codices) made their synodic periods end on Cipactli, Coatli, Atl, Actl and

Ollin, which correspond to the Maya Imix, Chicchan, Muluc, Ben, and Caban, while the Maya made theirs end on Kan, Lamat, Eb, Cib, and Ahau. The Aztec apparently did not employ any rule for correcting the annual calendar, and the uncertainty of the dates of their feasts seems to show that they were irregularly corrected from time to time when the discrepancy with the seasons became too great. Therefore we may assume that they did the same with their Venus calendar. In this case the formal calendar was much nearer to the facts than the annum calendar was, and the discrepancy therefore not so obvious. The actual discrepancy is about 5.2 days in two Calendar Rounds (104 vague years).

If Atamalqualiztli fell on 16 or 20 Tepeilhuitl in 1548, then, allowing for corrections (probably irregular and unsystematic but roughly accurate) of about five days every two Calendar Rounds, it would have fallen in Quecholli in 1544 in the reign of Montezuma I and probably during a long period of time previous to that. This would explain the statement of Sahagun that it was sometimes in Quecholli and sometimes in Tepeilhuitl. It had got into Tepeilhuitl only about the beginning of the current Venus cycle and had been in Quecholli ever since the first Calendar Round recognized by Aztec history, namely that which commenced in 1091 after the departure from Aztlan.

PORTARLINGTON, IRELAND

An Inscription on a Jade Probably Carved at Piedras Negras

Tatiana Proskouriakoff

Finely carved jades were doubtless regarded by the Maya as objects of great value. They could be passed on from generation to generation and could be traded in distant parts. In most cases one cannot rely on the circumstances of their discovery to evince their origin, and often the only clue is the style of the carving itself, at best an uncertain criterion, especially since conclusions must be based largely on analogy with arts of different technique. Fortunately, a few jades were inscribed with dates, and when these dates can be related to inscriptions on monuments they sometimes furnish more reliable evidence than does either style or stratigraphy. The piece described here is one of the rare examples which can be dated and placed with reasonable certainty, even though the Old Empire site of Piedras Negras, whence it came, has no known historical connection with the distant city of Chichen Itza where it was found among the offerings of the famous Sacred Cenote. It is now in the Peabody Museum of American Archaeology and Ethnology in Harvard University and is here described and reproduced with the kind permission of the Museum.

The jade is about 8.5 cm in its greatest dimension and is carved in half-round to represent a human head wearing an animal (serpent or jaguar) headdress. The style is idealistic and keenly sensitive to natural form, qualities characteristic of the best period of classic Maya sculpture. The back of the head is hollowed out, as if to reduce its weight, and along the flat edge of the hollow and on the top of the headdress runs an inscription of lightly incised

hieroglyphs. Five holes drilled with a pointed tool probably served to fasten the ornament and to attach to it beads or other embellishments. One of the holes was drilled through a glyph apparently after the inscription was made. This tends to confirm the assumption, otherwise not susceptible of proof, that the glyphs and the carving are contemporaneous.

The head resembles ornaments worn by the principal figure of Maya stelae, particularly the ornamental heads attached to the figure's belt. On such ornamental heads, the animal headdress occurs most frequently in the early period (cf. Stelae 9 at Tikal, 27 at Yaxchilan, E and 3 at Copan). Later, the headdress is replaced by a simple knot with its ends falling to each side of the face, but it recurs sporadically, as on Stela C at Copan and on Stela 5 at Tikal. At Piedras Negras, however, several stelae of the Late Classic period have ornamental heads with the animal headdress (see Stelae 2, 4, and 13). On Stela 10 at this site such a head is particularly clearly depicted as an ornament on a cushion. Although the features, shown in front view and in low relief cannot be compared with fairness to the full-round carving of the jade, in a general way it may be worth while to note that the excellent sculptural tradition of Piedras Negras, including as it does sculpture in the round, is entirely consistent with the style of the Cenote carving, which, especially in profile, is reminiscent of the faces portrayed on Piedras Negras stelae.

The connection of the jade head with Piedras Negras, however, is more clearly demonstrated by its inscription. The text begins on the top of the

headdress with two horizontal rows of glyphs: Although one dot of the day number is missing, the first two glyphs clearly record the Calendar Round date 7 Imix 14 Mac. The finer details of the month sign are obscure, but the elements characteristic of Mac are unmistakable. The next glyph is a familiar hand-and-tassel ending sign followed by 13 tuns (first glyph, lower line), and two glyphs of unknown meaning. From this record the unexpressed beginning of the count can be calculated as 7 Imix 19 Pax. On the back, the inscription is resumed at the lower left, but here a piece is broken out and the first three glyphs are missing. The fourth records 7 tuns, which, if added to the preceding date, reach 5 Imix 19 Zac, recorded by the sixth and seventh glyphs. The bars of the month numeral are depicted here by single lines instead of by full outline, but it is fortunately quite clear that the ends of these lines are not connected and there is no doubt that the number 19 was intended. Another hand-and-tassel ending sign follows and the record of one katun. The tun element is obscured by a break, but the coefficient and the comb elements flanking a cartouche can be readily made out. This establishes the date as a katun anniversary, referring to the previously calculated beginning of the count, 7 Imix 19 Pax. The meaning of the last glyph, which has a ben-ik superfix, and of the two glyphs below the border is unknown.

The same Calendar Round positions define an important katun anniversary at Piedras Negras. The earlier date 7 Imix 19 Pax is carved on Stelae 3, 7, and 8 in the Long Count position 9.12.14.13.1. The terminal date 5 Imix 19 Zac (9.13.14.13.1) occurs on Stela 1 and also on Stela 8, where it is specifically stated that it marks the end of one katun. The explicit notation on Stela 8 and on the Sacred Cenote Jade that 5 Imix 19 Zac is a katun anniversary makes it, in my opinion, virtually certain that both refer to the identical katun, and establishes also the Long Count position of the first date inscribed on the jade as 9 13.7.13.1. Moreover, if this argument is sound, the probability that the jade was carved and inscribed at Piedras Negras must also be accepted, for the dates involved seem to have a particular importance at the site and do not occur, so far as I know, anywhere else.

A brief summary concerning the distribution of Calendar Round dates in the Maya area may serve to clarify the justice of this contention. The following data are abstracted from a list of 372 different Calendar Round positions recorded or implied on Maya monuments and are compiled from the dates mentioned in *The Inscriptions of Peten* (1938) and *The Inscriptions at Copan* (1920) by S. G. Morley, supplemented by a number of dates from Palenque. Although this list does not include all known Old

47.1. Jade head from the Sacred Cenote at Chichen Itza; cat. no. C6100, Peabody Museum of American Archaeology and Ethnology, Harvard University.

Empire inscriptions, it covers fairly completely a large part of the Maya area and reveals certain definite tendencies in the distribution of dates. Dates falling on the day Ahau are not included since this day occurs on all period endings and also since its greater frequency increases the chances of its fortuitous repetition. Of the 372 different Calendar Round positions noted, 40 are repeated in some other text, and since some are repeated in several texts the total number of repeated notations is 66. By far the greater number of these repetitions, 62 occur at the same site as the original notation, and represent the same Long Count position in every case that it can be determined. Morley cites several Calendar Round anniversaries at Yaxchilan, but his interpretation of these dates is based on stylistic criteria which he does not state explicitly, and his conclusions seem to me to be open to serious doubt. I

should like to stress parenthetically the importance of this apparent association of dates with particular sites, for it seems to be neglected by some students who attempt to base arguments on the assumption that Maya dates represent records of astronomical observations. If conspicuous configurations in the sky were habitually recorded, eclipses and other dramatic celestial events would have been observed and noted simultaneously at many sites. Yet not a single date which could represent such a record is known. On the contrary, the most often repeated dates seem to have a purely local importance, suggesting that their significance was at least in part historical.

Only two prominent dates are recorded at more than one site: 9.15.6.14.6 6 Cimi 4 Tzec is inscribed on Stelae J, F, and E and Zoomorph G at Quirigua and on the Hieroglyphic Stairway at Copan; 9.12.10.5.12 4 Eb 10 Yax repeated at Naranjo on Stelae 3, 24, and 29 probably is the same date recorded on Stela 1 at Coba. The first of these instances can be explained readily by the geographical proximity and the cultural contact between the two sites. The second is perhaps a fortuitous exception, though a historical connection between Naranjo and Coba is suggested by many similarities in their sculptural and architectural styles (Thompson, Pollock, and Charlott 1932).

The two remaining repetitions seem to be chance occurrences of the same Calendar Round position in different Calendar Rounds. One is the date 9 Eb 10 Tzec. On Lintel 12 at Piedras Negras it is written as an Initial Series 9.3.19.12.12 and on the Hieroglyphic Stairway at Copan as 9.14.10.10.12. The other is 2

Eb 0 Pop. Its Long Count positions are not entirely certain but seem to be 9.10.3.2.12 at Naranjo on the Hieroglyphic Stairway of Structure B-XVIII and, according to Thompson, 9.19.1.5.12 on Altar U at Copan. Such apparently unconnected repetitions can be expected to occur by chance at rare intervals, and the curious fact that both dates cited fall on the day Eb is probably a mere coincidence.

This brief résumé of the facts furnishes the basis for placing an unconnected Calendar Round date in the Long Count series and associating it with a particular site. In my opinion, the evidence in the case made for the jade of the Sacred Cenote is so strongly reinforced by the explicit record of the katun anniversary that it may safely be accepted as virtual proof that the piece came from Piedras Negras.

The actual date of the carving is not so readily determined, but, in the absence of stylistic indications to the contrary, it might be considered as roughly contemporary to the monuments recording the same dates, i.e. within the katun between 9.13.15.0.0 (Stela 1) and 9.14.15.0.0 (Stela 8). Unfortunately we do not know when and by what route this perfect example of Old Empire lapidary art reached the city of Chichen Itza and how it came to be deposited in the Sacred Cenote. Were they recoverable, the facts of its history might prove highly significant, for such easily portable and almost imperishable objects could have exerted long-lasting and far-reaching influences on later sculpture by preserving the continuity of artistic traditions even after the southern Maya cities were abandoned and their larger monuments no longer were available for study.

Costumes and Wedding Customs at Mixco, Guatemala

Lilly de Jongh Osborne

Santo Domingo Mixco is a Pokoman-Maya village in the Department of Guatemala, 15 km west of Guatemala City. Despite the proximity of the capital and many Cakchiquel villages in the immediate vicinity, the Pokoman of Mixco still retain many of their old customs, particularly those relating to the important ceremonial occasions such as baptisms, weddings, and burials.

The women have changed their everyday costume considerably, but for great ceremonies they still keep to the old traditions. The everyday costume is distinguished by a well-made huipil, woven either in Quetzaltenango (although in only two sections instead of the three of the Quetzalteca's costume *de rigueur*) or in San Pedro Sacatepequez. The latter is white with multicolored figures and is made for sale in Mixco and other villages. The *refajo* or skirt, about 7 yards wide, is pleated in imitation of the skirts worn by the ladies of the sixteenth and seventeenth centuries. It has from three to five bands of narrow ribbon or braid encircling the hem about 10 inches from the edge. The material is nondescript, but for best wear it comes from the highlands and has many tie-dyed designs in the best technique obtainable: white designs on red, yellow, and green background.

For special occasions such as weddings and burials the costume takes on particular significance. The *refajo*, as described above, has a trimming of velvet ribbon around it. The huipil must be one which has been woven at San Martin Jilotepeque in the local style, dark blue, almost black, founda-

tion in basket weave with multicolored designs in silk or, nowadays, rayon covering the surface and distinguished by the peculiar San Martin dots made by placing extra pattern yarns under and over three different filler yarns, cut off short on the right side of the textile. The whole has a tapestry-like and gay appearance.

Forty years ago no self-respecting Mixco woman would have worn any but the typical Mixco belt, but this has disappeared almost entirely and is now regarded as a precious heirloom. These magenta and white or purple and white belts, woven in Oaxaca, Mexico, were brought to Mixco by traders. For ceremonies the hair is arranged in one long braid with very long *tocoyales* (strands of wool) in magenta or red. The whole is wound around the head to form a halo. Rings, earrings, and a short bead chain complete the costume for a girl about to be married.

Overpopulation led to the migration, just before the conquest, of a part of these Pokoman from their homes in Cuzcatlan to Guatemalan territory, where they settled between the lands of the Cakchiquel and Sacatepequez nations. They soon constructed a fortress city near the present San Martin Jilotepeque. The conqueror of Guatemala, Pedro de Alvarado, subdued these Indians, some of whom he settled in the aforementioned San Martin. The greater part he moved in 1526 to the present site of the village of Mixco. The old fortress is now known as Mixco El Grande or Mixco El Viejo.

It may be of interest to mention briefly how the *costumbres* for a marriage are carried out. The young

**a****b**

48.1. Huipils at Mixco, Guatemala: (a) everyday huipil; (b) wedding huipil made in San Martin Jilotepeque.

man's parents and the principal men of the village arrive on a prearranged day at the hut of the girl's parents. In front of the closed door, they kneel and pray, lighting the tall candles (worth at least 5 cents each). When they have concluded their prayers, they say in unison "*Ave Maria Purisima*," to which the girl's family responds from behind the closed door "*Sin pecado concebida*"; and the boy's delegation returns home. This function is called *la razon*.

On the second visit the boy's sponsors are admitted. They bring gifts of beer, liquor, and candles, and,

after discussing the weather, the crops, and the hard times the world is going through, they finally mention the reason for their visit. They retire, assured that the matter will be considered. At the third visit, also accompanied with liquor, the answer is given that the arrangements may proceed for wedding in at least three months' time.

Now follow other costumbres. The first visit of this second series (*el pedimento*) involves more expense for the young man's family. Friends and relatives arrive in ceremonial clothes on a given

Sunday. A special kind of bread is wrapped in a *chivo* (a small cloth with loops at intervals all over the surface) woven of the natural brown cotton known as *cuyuscate* or *ixcaco*. The bundle is carefully examined by two members of the girl's family, who discover five quetzales (formerly gold coin) under the bread, and report that it is all according to "costumbre." The rest of the basket is filled with chocolate, which they proceed to brew and drink with their guests.

The second visit of this series likewise requires an outlay of drink, chocolate, bread, etc. Further plans are made for the wedding, and the young man's ability to maintain the girl is discussed. On the third and last visit five quetzales and ceremonial sweet bread are again presented and in turn examined, to be sure that the gift conforms with custom. At this function a large turkey, well seasoned with many peppers, is brought as a final offering of good will towards the girl's family. I have known a wedding to be much delayed because the boy's family, which belonged to an outlying district, had lapsed in etiquette, for they proposed to present the turkey on the wedding day instead of at the third pedimento. Once they were informed of the proprieties, they arrived speedily a couple of Sundays later with a gigantic turkey, and the final arrangements proceeded.

On the wedding day the bride's godmothers dress her in the costume already described. Nowadays old customs are vanishing, and some brides appear even in ladino-wedding costume, complete with artificial wreath of flowers and white wedding veil.

The godmothers wear their best and widest refajos. Older women wear the enormous tocoyal head-dresses. These have a ceremonial significance and consist of a veritable mountain of black, purple, and red interwoven wool strands, over which is thrown a hand-woven sheer white textile in a veil effect. The fat candles these women carry in their hands are wrapped halfway up in canna leaves.

After the Roman Catholic service in the village church, the wedding party repairs to the girl's home. At the entrance the young couple kneels in front of their elders. The father and oldest godfather then proceed to admonish them at length on their future obligations to each other and to the community, stressing adherence to their *costumbres*, particularly in relation to the idea of their fertility and that of their crops. After this lecture refreshment, especially tamales and intoxicating liquor, is consumed.

Refusal of consent to the marriage for some reason or other by the girl's parents is considered a bad omen for the girl and her family. She will probably never again be asked in marriage, and must either work hard to maintain herself or form an alliance with some man not contemplating marriage, without all the beguiling prenuptial *costumbres*.

The San Martin Jilotepeque huipil used during the wedding ceremony is carefully put away and used only for burial. It is considered a sign of very hard times if a woman wears this huipil except perhaps for some great ceremony. It is quite unthinkable to sell it.

GUATEMALA CITY

Combinations of Glyphs G and F in the Supplementary Series

Sylvanus G. Morley

The two glyphs known as G and F were once believed to have formed part of the Lunar or Supplementary Series. In the past ten years Thompson (1935:84–85; 1940; 1944) and Beyer (1935a–b; 1939) have called attention to occurrences with Calendar Round dates of either Glyph G alone or, less frequently, of Glyphs G and F together. In such cases they stand between day and month signs, and are completely dissociated from any Lunar Series.

The purpose of this paper is to bring together further evidence that Glyph F is not a part of the Lunar Series.

In 1931 I noticed on Stela 52, Calakmul, an unusual combination of Glyphs G and F of the Supplementary Series (Fig. 49.1i), in which the essential element of Glyph G9 (Fig. 49.1n), the kin sign, appears incorporated with the affixial elements of Glyph F, specifically the latter's diagnostic superfix and suffix (Fig. 40.1m). This intermingling of elements from the two glyphs would indicate some close relationship between them, at least that they are members of the same group. Since Glyph G has been surely shown by Thompson to belong with the Initial Series, it follows that Glyph F also probably belongs with the same count and not with the Supplementary Series, as I originally believed.

The commonest form of Glyph F is composed of three elements: a highly distinctive superfix, itself divided into three parts; a central element which is clearly a knotted band; and a suffix which is as characteristic as the other two elements (Fig. 49.1m). We shall see that when Glyphs G and F are combined, it

is usually the first and third elements of Glyph F that are retained in the combined FG forms, the second (the knotted band) element being eliminated.

In 1936 Hermann Beyer (1936b) cited four cases of Glyphs G8 and F combined: two from Palenque, one from Yaxchilan, and one from Copan (Fig. 49.1d–g). It will be noted that in three examples the superfix and suffix of Glyph F have been retained in the combined forms; the central element only having been replaced by G8. In the fourth example, from Yaxchilan, the knotted middle element replaces the usual suffix. The association of the essential elements of these two glyphs in a combined form indicates a correspondingly close relationship between them.

Recently Heinrich Berlin (1943) has published a new Palenque text in stucco showing Glyph G3 combined with Glyph F (Fig. 49.1b). In spite of the fact that the F superfix is on a still missing fragment, there can be little doubt that it was originally present. Berlin calls attention to another GAF combined form at Palenque, also from the same building, the Temple of the Sun (Fig. 49.1a). There is a third example of Glyph G3 at Palenque, but not combined with Glyph F (Fig. 49.1l). A comparison of this last glyph with figures 1a and 1b will show how, the superfix and suffix of Glyph F (Fig. 49.1m) have been retained in the combined glyph, and the knotted band central element eliminated.

The above six examples are those of Glyphs G and F of the Supplementary Series combined in a single glyph in each case: two examples of Glyph G3

49.1. Glyphs G, F, C, and A of the Supplementary Series. Glyphs G3 and F combined: **(a and b)** Palenque, Temple of the Sun. Glyphs G5 and F combined: **(c)** Calakmul, Stela 89. and F (Fig. 49.1a, b) and four examples of Glyphs G8 and F (Fig. 49.1d–g).

Recently I have re-examined all the known Supplementary Series, 296 in number, and find six other examples of these combined forms of Glyphs G and F: one of G5 and F (Fig. 49.1c) and five of G9 and F (Fig. 49.1h–k, o). In the latter combined forms (G9 and F) the three shells usually found as the superfix of the kin sign in G9 (Fig. 49.1n) are suppressed in four cases but are present in the fifth.

In the twelve known cases of these combined GF glyphs noted, there are two examples of combined forms of G3 and F, one of G5 and F, four of G8 and F, and five of G9 and F. These are distributed as follows: four at Palenque (Temples of the Sun [twice], Cross, and Foliated Cross), two at Copan (Stela 10 and Temple 11), two at Calakmul (Stelae 52 and 89), two at Yaxchilan (Stela 11 and Lintel 21), and one each at Piedras Negras (Stela 10) and Naranjo (Stela 30). The heaviest concentration is in the Usumacinta Valley, where Palenque, Piedras Negras, and Yaxchilan have seven of the twelve examples found.

The earliest occurrence of a combined G and F is in the Supplementary Series of the Temple of the Sun, Palenque, dedicated in 9.10.10.0.0, where Glyph G3 is combined with Glyph F (Fig. 49.1a).

Of the 79 certain, simultaneous occurrences of Glyphs G and F in the Supplementary Series, there are twelve examples of these combined forms. However, if all the probable simultaneous occurrences of these two glyphs are included, the percentage of the combined GF forms would be less.

This combination of two different glyphs of the Supplementary Series has a precedent in the case of two other glyphs of the same count: Glyphs A and C. Two combined forms of these signs have been found at Piedras Negras (Stela 25 dedicated in 9.8.15.0.0 and Stela 26 dedicated in 9.9.15.0.0).

On Stela 25 Glyph 3C (Fig. 49.1r) is combined with Glyph 9A (Fig. 49.1t) in such a way that the moon sign in Glyph 9A is suppressed; its coefficient of 9 being attached as a postfix directly to Glyph 3C (Fig. 49.1p). In the case of Stela 26 Glyph 5C (Fig. 49.1s) is combined with Glyph 9A in such a way that the moon sign in Glyph 9A is suppressed, its coefficient of 9 being attached as a postfix to Glyph 5C (Fig. 49.1a). The meaning of these two glyphs clearly establishes their close connection as belonging to the same count, i.e. the Supplementary Series.

The association of Glyph F with the Initial Series rather than with the Supplementary Series is further demonstrated by its position. In the 79 cases when Glyphs G and F both surely occur, Glyph F always immediately follows Glyph G with no other glyph

standing between them, whereas in four of these cases, two at Palenque (Temple of Sun), and on Temple 11, Copan, and Stela 12, Altar de Sacrificios, the month of the Initial Series terminal date immediately follows Glyph F, thus bringing together in uninterrupted sequence all ten glyphs of the Initial Series, followed by the six glyphs of the Supplementary Series, also in uninterrupted sequence.

Why the six glyphs of the Supplementary Series should stand between the last two glyphs of the Initial Series, i.e. Glyph F and the month of the Initial Series terminal date in the majority of cases, instead of immediately following the latter as in the cases of the four examples just cited, is perhaps due to the desire to have the month of the Initial Series terminal date stand as close as possible to the current lunar month of 29 or 30 days, i.e. immediately following it, and perhaps even more, to indicate by thus enclosing the Supplementary Series within the Initial Series that, as Bowditch originally suggested, it “supplements” the Initial Series. This indeed it does, giving the lunar date corresponding to the Initial Series date in each case.

This elimination of Glyphs G and F from the Supplementary Series reduces the standard Supplementary Series to six glyphs, E, D, C, X, B, and A. Of these, E, D, C, and A incorporate the moon sign. Glyph X occasionally has a moon sign in one of its six variants (Form 4); Glyph B has the head of a rodent as its principal element, an animal clearly associated with the moon in the sculptures of a number of cities. Thus the internal evidence presented by the six glyphs of the Supplementary Series, to say nothing of the mathematical proof thereof, strongly suggests that this is a lunar count.

Teeple (1931:63) has suggested that in view of the fact that Glyph B of the Supplementary Series never has a numerical coefficient of any kind but frequently has an “ending” prefix or superfix, its meaning is general and does not specifically affect the lunar count presented by the other five glyphs of the Supplementary Series.

I believe that since Glyph F of the Initial Series never has a numerical coefficient, its meaning, too, is general, and in no way affects the diurnal count presented by the other nine glyphs of the Initial Series, of which it is the penultimate glyph. Although Glyph F has no “ending” superfix or prefix like Glyph B of the Supplementary Series, its central element is a knotted band (Fig. 49.1m) or, more rarely, the kin sign itself (Fig. 49.1c). And as used in Glyph F this knotted band perhaps signifies it is “tied up,” or “closed,” or more generally “here ends the day count” (i.e. the Initial Series).

Moon Age Tables

Lawrence Roys

Following Goodman's idea of giving Maya dates in tabular form, I present here two charts which link the age of the moon to a series of Maya dates.

The first, and simpler of the two, needs little explanation beyond the legend. The dates shown in the chart are of conjunctions five lunar years apart. Intermediate conjunctions, or new-moon dates, can be determined by interpolation. It is suited to problems handled best with our decimal system, and demands the preliminary step of converting Maya vesical dates into decimal counting, conveniently defined as Maya Day dates by R. W. Willson (1924:17). This table is convenient for such problems as checking time intervals from the inscriptions against intervals between new moons, and for general use where it is easier to think in terms of our modern arithmetic. Of course, the moon age for any Maya date can be easily found with its aid.

The second and more extensive table provides a quick method for obtaining the desired moon age for a given Maya date without converting it into Arabic notation. It is a series of Long Count dates, each accompanied by its moon age. They are close enough together to yield a date of known moon age conveniently near any given date of which the moon age is unknown. Further columns are added so that the chart may be used for other general work.

The detailed steps for finding the moon age for a given date, e.g. 9.5.6.14.3, are as follows:

1. Take from the 5-tun chart the Long Count date immediately preceding the given date, and trans-

fer this with its moon age to a work sheet. E.g. 9.5.5.0.0, moon age 5 2/10.

2. Find the distance between these two dates by subtraction. E.g. 9.5.6.14.3 minus 9.5.5.0.0 equals 1.14.3.
3. Referring to the multiplication table at the side of the pages, select the highest multiple that does not exceed the remainder just found in Step 2. E.g. select 1.13.0 1/10 which is less than 1.14.3.
4. This highest multiple should be subtracted from the remainder found in Step 2. E.g. 1.14.3 minus 1.13.0 1/10 equals 1.2 9/10 (22 9/10 days). (This fourth step is a condensation of two arithmetical operations, and in effect gives us the distance that our given date lies beyond an intermediate date whose moon age is 5 2/10. With such a distance reduced to less than a month, it becomes hardly more than a matter of inspection finally to determine the moon age for our given date. The actual figure for the intermediate date does not appear in this solution as it has canceled itself out.)
5. To the remainder just obtained in Step 4 should be added the moon age from the 5-tun chart obtained in Step 1. E.g. 1.2 9/10 plus 5 2/10 equals 1.8 1/10 (28 1/10 days). This gives the unknown moon age desired for our given date. If this final answer exceeds 29 1/2 days, it can be corrected by the simple expedient of subtracting 29 5/10 days.

The computation on the work sheet appears as follows:

Given Date	9.5.6.14.3	
1. 5-tun chart date	9.5.5.0.0	. . . of moon age 5 2/10
2. Remainder	1.14.3	
3. Highest multiple	1.13.0	1/10
4. 2d remainder	1.2 9/10	(or 22.9 days)
5. Moon age from (1)	5 2/10	(or 5.2 days)
5. Desired moon age	1.8 1/10	(or 28.1 days)

After a little practice, only the last five lines need be written down as the first simple subtraction can be solved by inspection.

Hyphens are used here before the kin and the uinal so that tenths of days can be written decimally without causing confusion. This is after the manner of Teeple, but adopted solely for convenience in figuring and not as an interpretation of Maya thought as Teeple has used them. In the preceding explanation, I have used vulgar fractions to show tenths, but only for purposes of clarity. The user of these tables will almost certainly prefer to shift to decimals, and the use of hyphens will aid this.

A word should be added to explain the need of tenths of days in these computations, a seeming over-refinement where the probable error often exceeds a full day. For comparative work, this is necessary in order to avoid absurd results. For example, 1,294,106, minus 1,294,104.6 gives an interval of 1.8 days which is practically two days. If the decimal were ignored, we would round out the numbers to 1,294,106 minus 1,294,105 and obtain a difference of only one day.

In planning these charts, I had a serious problem properly to correlate a series of new-moon dates 1771.836 days apart with the new-moon dates indicated by moon ages recorded in the inscriptions. The latter agree in only a general way with the results produced by an exact lunar calendar, sometimes varying three days or more either way from a table based on their average positions. Teeple attacked this problem from more than one angle, first favoring 9.16.4.10.9 as a new-moon date (1925a:114). At another time he favored 9.16.4.10.7 (1925b:549), but his final judgment was midway between these two and he gives 9.17.0.0.0 as his preference (1931:53). This last is practically the same as a new moon at 9.16.4.10.8, the date which is thought to introduce the remarkable eclipse calendar of the Dresden Codex.

At present we can only guess at the reasons for the wide variations. Teeple reasoned that the records in the inscriptions were observational, and affected not only by cloudy weather but even by the pos-

sibility that the observing priest's mind may have been clouded at times. Granting the plausibility of this, one cannot help wondering how to account for a spread as great as five or six days in recording as conspicuous a phenomenon as the first appearance of the new moon. When actual lunar conjunctions are compared with a table of average conjunctions exactly 29.5306 days apart, they are found to swing over a range of plus or minus 6/10 days from average. To this swing should be added any lag due to conjunction hour preceding sunset hour by part of a day (Teeple mentions both items). By combining extreme positions for both of these factors, a maximum range of about 2.2 days can be obtained; and other astronomical variations and weather could probably increase it to three days. However, this is far short of the range of about five days necessary to include the bulk of the data that need to be accounted for. Teeple's explanation looks probable, but does not dispel all doubts. However, no better hypothesis has yet been advanced.

Although the situation is puzzling and somewhat unsatisfactory, we must decide upon a definite base for these charts. With this purpose in view, we graphically plot the swing in new-moon positions for practically all of the published inscriptions where the Long Count dates have been determined with a fair degree of certainty, and are accompanied by Lunar Series giving the moon age. Teeple (1931) and Morley (1938) supply 108 such dates. We tentatively assume with Teeple that 9.17.0.0.0 was a new-moon date. We have 108 new-moon dates shown by Glyphs D and E in the inscriptions, and we can obtain from this Teeple formula a corresponding expected new-moon position for each of them, i.e., an ideal new-moon position that is distant from 9.17.0.0.0 by an even multiple of 29,5306. Obviously the deviations of the new-moon dates shown by Glyphs D and E from the expected new-moon positions give us the needed data. The data were plotted some years ago. More recently four or five of the readings in the lists have been shown to be erroneous. The rectification of those few errors would not materially affect the conclusions, and the chart has, accordingly, been allowed to stand as it is.

Examination of Figure 50.1 is interesting. Commencing with 9.9.15.0.0, we have 86 recorded new moons and find that the arithmetical average of their deviations from Teeple's formula is exactly zero. However, we get quite a different picture when we work backward from 9.9.15.0.0. We have only 22 recorded new moons, but their arithmetical average deviation is 1.4 days below our Teeple formula; and their range is narrower than that of the larger group. In spite of our limited number of cases, we have a

50.1. Deviations of recorded new-moon positions. These are shown vertically, each space representing a day. The Maya date is plotted horizontally. Here recorded are 108 cases beginning with 8.16.0.0.0 and ending with 10.2.9.1.9.

consistency which casts a doubt on the Teeple formula that we have tentatively selected.

If we wish, we can average the deviation for our entire 108 cases and revise our tables to fit this average, making a change of $3/10$ of a day all along the line. This does not greatly affect the later period, but still leaves a serious inconsistency in the earlier group. It therefore seems the wiser and possibly more conservative course to maintain Teeple's 9.17.0.0.0 formula throughout, with the reservation that previous to 9.9.15.0.0, Glyphs D and E are likely to show recorded moon ages about a day or more less than expected. The tables in this report are accordingly computed on this basis. This decision has the added advantage of conforming with Teeple's "Maya Astronomy" (1931), the accepted textbook on the subject. Of course this average new-moon position is tentative, and subject to correction by further data. However, I incline to the belief that the 9.17.0.0.0 formula will be serviceable for some time to come, particularly for dates subsequent to 9.9.15.0.0. It has the convenience of being a round number, and its closeness to the Dresden Codex Eclipse Calendar date, 9.16.4.10.8, makes it useful in working with that important document.

Interpretation of this plotted graph is not certain. It is possible that the lower average for the earlier period is basically in error and will ultimately be corrected upward by further extensive data for that period. However, our present data give little promise of such a correction. Considering the plot alone, the mathematical conclusion would favor the idea that about 9.9.15.0.0 there occurred a shift in the method of computing moon ages. Such mathematical reasoning alone is not convincing, but in this case it is supported by our knowledge that the Maya lunar calendar was in a state of flux not long afterward. Teeple's Period of Uniformity commenced about 9.12.15.0.0, only three katuns after the change here in our graph. In view of the mutual support of these two developments, it would seem that we should lean toward the idea that about 9.9.15.0.0, there was

a movement among the Maya priest-astronomers to shift their new moon dates to an earlier position, i.e., to bring them nearer to actual astronomical conjunction on the average.

Needless to say, this shift applied only to an average of positions, and was not accompanied by any reduction in the deviation of recorded new-moon dates from the average. In fact; the swing was even greater during the second half of Baktun 9, end remains an unsolved puzzle. I am far from being convinced that Teeple's explanation is correct, viz., that the new-moon dates were determined by actual first sight of the new moon. Although possible, it seems inadequate. Could not the matter be explained with equal probability by the suggestion that certain days were taboo as new-moon dates, and alternatives had to be found? I present this speculation largely as a warning against too complete acceptance of Teeple's plausible theory that actual first sight of the new moon was the complete answer. Naturally, the sole purpose of presenting these tables is to supply a ready reckoner. So far as their use is concerned, it is immaterial whether the Maya reckoned their moons from disappearance, conjunction, or appearance.

In closing, I should explain that I prepared the first of these tables in 1931. At that time I believed that 9.16.4.10.9 was very close to a new-moon date, and I computed the table showing new-moon dates a day later than are shown here. The table of 1931 proved to be very workable and convenient and seemed to require no correction up to the present investigation. A number of copies were given to friends and consequently it should be noted here that computations made with the 1931 table will vary 1.0 day from those made with the accompanying tables. This is not a matter of importance except where comparative work is being done. It should, however, be noted that all the lunar computations published by Morley (1920) were based on my old tables, and are therefore a day off those which would be obtained with the present tables.

Table 50.1. Table of New Moon Days, and Lunar Half Year Beginnings By “Maya Day” Reckoning

The Maya Day number is given for the beginning of every tenth lunar half year. By means of the tables at the right, the values for the individual half year beginnings may be obtained, and likewise those for individual new moon dates. The method is ordinary interpolation by arithmetical series. The interval for the main table is 1771.836 days.

A Second Tlaloc Gold Plaque from Guatemala

Karl-Heinz Nottebohm

It has been supposed until recently that one of the Zacualpa gold disks (Fig. 51.1a) originated in Peru and was of Chavin workmanship. Lately, however, the disk was said to represent the Mexican rain god Tlaloc, a claim which seems to be confirmed by a second and similar disk hitherto unreported (Fig. 51.1b).

Unfortunately the exact provenience of this new disk is not known, although it is believed to have come from the western part of Guatemala near the Mexican border. Probably it comes from a burial, as it shows a light red patina and traces of soil in some parts. The plaque is gold, circular, and, in contrast to the convex shape of the Zacualpa disk, flat. The diameter is about 11 cm compared to 12 cm for the Zacualpa specimen. Above the headdress can be seen two holes, the rims of which are carefully smoothed on the reverse side indicating that the new disk had been intended for an appendage just like the Zacualpa disk, which has similar holes at about the same place.

Both disks show the same treatment of the rim as well as similar kind of technique and artistic feeling in the repousse design. Irregular rays emanate from a line of dots paralleling the circumference. The subject depicted on the new plaque seems to be the same as that on the Zacualpa disk, which has been identified as the rain god Tlaloc. Characteristic

of the Tlaloc on the new disk are the orbital circles as well as the lip.

51.1. Gold disks from Guatemala: (a) Zacualpa region, after Lothrop; (b) attributed to western Guatemala.

Rock Paintings at Texcalpintado, Morelos, Mexico

M. A. Espejo

At the end of September 1943 some people from Hueyapan, Morelos, reported to the Mexican National Museum of Anthropology the discovery of a great number of figures painted on a rock at a place called Texcalpintado in the state of Morelos. With the permission of the director of the museum I went to see these paintings with Mr. R. H. Barlow and seven other persons.

The site is situated about 7 km south of Hueyapan. The River Amatzinac at that point is bounded on its left bank by a very high cliff. About 8 m above the stream there projects a small terrace, some 10 m long by 2 m wide. The pictographs cover the vertical face of the cliff immediately above this terrace, occupying an area 20 m long by 5 m high.

The figures are drawn in white against the slightly reddish background of the rock. In many places this white paint has aged to a yellowish tone. The average height of the figures is 40 cm. There are also numerous dots carved in very irregular horizontal lines. Some of these have been painted white. Apparently the paintings were made in strips at sundry levels, advantage being taken of the irregularities in the rock. There are, however, many isolated and unrelated figures.

Because of the narrowness of the platform it was impossible to copy all the designs, but all those of most importance are shown. A few of the reproductions reveal some distortion because of the angle from which they were copied.

The first group at the bottom of the left end consists of dots which, because of their crudity and

much weathering, appear to be the oldest. They occupy an area about 3 m by 3 m.

Above this band of dots there are, two heads, that to the right clearly being a representation of Tlaloc.

To the left and above there is an important group of three persons representing a scene. A man, wearing a low headdress like an *amacalli* (bark-cloth hat) with two quetzal feathers, carries the ceremonial rattle in one hand. A woman is seated before him with two spots on her cheek, clearly facial decoration. Below her is the third figure with face painted with a vertical line behind his eye.

This scene appears to continue in another group which is not in line, owing to the irregular surface of the rock. There are three principal figures here. The first and second carry an *amapamitl* (stick with two strips of paper), the first wearing a sort of three-pointed crown very similar to that, which Tlaloc sometimes wears. He has a crescentic mark on his face. The third figure is a man wearing the mask of a bird.

Higher still (and there is consequent distortion in the copy) there is a man wearing the mask of some wild animal. At his feet is a small human figure carrying a jar on his head.

In the center of the area there are a number of figures, of which the most important is that of a man carrying a rattle and wearing a headdress which also is probably an *amacalli*. South of this are to be seen crossed bones very similar to those in Mixtec codices, the head of an owl reminiscent of those on the stelae of Monte Alban, a warrior with a shield and

52.1. Rock paintings at Texcalpintado, Morelos, Mexico.

52.2. Rock paintings at Texcalpintado, Morelos, Mexico.

two arrows, and another face which might represent Ehecatl.

The last group, at the top of the south end, appears to be the most recent because the white paint is brighter. It consists of a circle with a banner on top, an animal, and a woman. The animal, which is to the left, has a very long snout; the woman, to the right, has a very elaborate headdress, and carries in her right hand two objects like ears of corn.

A circle with a banner above it is the glyph for Hueyapan in the Mendoza and other codices.

Because of the sundry styles, from the simplest and most conventionalized to those close to realism, it is probable that these pictures are the products of diverse groups which utilized this rock at different periods.

The crossed bones and the owl represent southern influences, Mixtec and Zapotec respectively. There are several Tlaloc heads and Tlaloc symbols and paraphernalia, such as the jug and the *amapamitl*. The figure wearing the mask of the wild animal might represent Tepeyolotli or Huehucoyotl, since both are shown in the codices seated and with a little man at their feet, as in the petroglyphs. The rattles suggest the Xipe cult, although these are also carried by various deities of the soil. The last figure described might be the goddess of maize. There is also a glyph of Venus, and numerous symbols of sacrifice, such as banners and crossed bones.

The drawing was made by Mr. Barlow, whose advice I have also sought on the interpretation of some of the figures.

INSTITUTO NACIONAL DE ANTROPOLOGIA
MEXICO, D. F.

A Pyrite Mirror from Queretaro, Mexico

Gordon F. Ekholm

The pyrite mirror described herein holds considerable interest because of the technique of manufacture and the nature of the carved design on its reverse side (Fig. 53.1). It was acquired by the American Museum of Natural History (Cat. no. 30.1-618) in 1931 along with a small collection of other objects. Information as to its exact place of origin is lacking, but we can rely with some certainty on the testimony of the collector that it was found in an excavation at an archaeological site near the town of Tequiacuapan in the southeastern portion of the state of Queretaro.

The mirror is a round plaque, 15 cm in diameter and 7 mm in thickness at the center. The reflecting surface is a consolidated mass of small pyrite crystals approximately 1 mm in size, whereas the back is a hard and fine-grained black slate that bears a carved design. A particularly interesting feature is the fact that, contrary to most disc mirrors from the New World, the pyrite surface is not composed of a mosaic cemented on a stone base. The entire object is cut from a single piece of material, the slate and the pyrite being naturally juxtaposed layers. Supposedly a block of material was found which was composed in part of slate and in part of pyrite, and this was cut to form a disc with the different substances on its two sides.

The slate and pyrite layers are quite distinctive materials, differing in color and texture, and are divided sharply in a generally straight line to be seen running around the edge of the plaques. The two substances adhere tightly except at one place on the edge where they have become slightly separated.

The whole gives the appearance of two separate plaques skillfully smoothed and cemented together, but such would have been an almost impossible feat without the use of modern tools. That this could not have been the method of manufacture is further confirmed by the fact that the line of puncture is slightly wavy, indicating, apparently, that such was the surface of the original slate mass before the pyrite was deposited against it. The slate layer varies from 2 to 3 mm in thickness; the pyrite layer from 3 to 5 mm.

The principal features of the disc can be seen in the illustration. There are twenty holes near the periphery, which, on the mirror side, are definitely triangular but on the reverse side approach circular form. There are also two pairs of biconically drilled holes, supposedly for the attachment of the mirror by the use of cords. They are strangely placed diagonally to the axes of the design. The edge of the reverse or decorated side is evenly beveled; there is a lesser notched beveling as the mirror side. The pyrite surface is slightly convex, with most of the curvature near the edges, the central area being relatively flat. The central area has a higher polish than have the portions near the edge, but this seems to be largely a matter of better preservation. Because of its slight disintegration and because it is partially covered with a brown stain, the mirror gives no reflection at the present time.

The reverse or slate surface, which is flat and smooth, bears an incised design. The carving is somewhat crude, done by a hand not entirely under control, as seen in the irregular curves and the places

53.1. Pyrite mirror from Queretaro, Mexico: (a) reverse or slate side; (b) pyrite or mirror surface.

where the tool has slipped. There is a lack of finish, for the tool-marks in the cut-away areas have not been smoothed down. It will be noted also that the design is not well adjusted to the circle of perfora-

tions, which were probably made after the carving of the surface had been completed.

The design shows two individuals, apparently male and female, facing each other and standing on a decorated platform. They are holding between them what appears to be a pottery vessel from which either a plant or conventionalized smoke emerges. Both figures have elaborate headdresses. Between and beside the two figures, as though forming a background, are two double scrolls characteristic of the design called "Totonac." It is the kind of scroll-work that is common, for instance, to many of the decorated stone yokes and is used profusely on the walls of the ball court at Tajin.

Our mirror, having been found in the state of Queretaro, is an interesting occurrence of this "Totonac" element farther to the northwest than any previously noted, but another comparison may be mentioned. The carved design on our disc closely resembles that on another mirror found by A. V. Kidder in a tomb of the Esperanza phase at Kaminaljuyu in highland Guatemala. Illustrations of it will appear in his forthcoming report on this site, wherein the similarity of its design to that on our piece from Queretaro may be observed. For the time being, however, I wish to point out that the carving on the Kaminaljuyu mirror also has two facing figures with a "plant" emerging from a jar between them and with elaborate ornamentation in the so-called "Totonac" motif. The carving is likewise done in a black slate, but the mirror surface is formed in the more usual manner by a mosaic incrustation of pyrite.

Among the other objects in the collection to which the Queretaro mirror belongs is a cylindrical tripod vessel of the form common to Period III at Teotihuacan. We have no information as to the possible association of these two pieces, but supposedly they came from the same site. They certainly could have been associated because the similar mirror from Kaminaljuyu is from the Esperanza phase, definitely contemporary with the Teotihuacan III horizon.

As far as I am aware, mirrors of this kind, formed from naturally cemented layers of slate and pyrite, have not been described heretofore, although Dr. Kidder informs me that there are others in existence in the Museo Nacional of Mexico. They are interesting technologically, indicating an unusual cleverness in the selection and use of materials.

Informe sobre la existencia de jugadores de pelota mayas en la cerámica escultórica de Jaina

Salvador Toscano

Durante la última visita que J. Eric S. Thompson realizara a México, tuve oportunidad de informarle de la existencia de dos figurillas de barro, procedentes de la Isla de Jaina, Campeche, representado jugadores de pelota, informe que venía a completar su noticia sobre un jugador de pelota maya modelado en un silbato encontrado en Quintana Roo. Como al Sr. Thompson le pareciera de interés un informe de esta naturaleza para las *Notes on Middle American Archaeology and Ethnology* de la Institución Carnegie, me invitó a que las describiera y reprodujera en las mencionadas *Notes*.

En efecto, la presencia de jugadores de pelota en relieves mayas fué por vez primera advertida por Blom. El tema ha sido más tarde suficientemente esalarecido por Thompson, quien llegó hasta a describir las famosas estelas pipiles de Santa María Cotzumalhuapa, Guatemala, como, escenas religiosas en conexión con el juego y el frontón al que debieron exornar. Igualmente el Sr. Mario Mariscal ha tocado el tema de las representaciones en bajorrelieves de jugadores de pelota. Ahora, por lo mismo, no sólo conocemos las representaciones pictográficas (aztecas y mixtecas) de los códices, sino lápidas, altares marcadores, etc., con representaciones en bajorrelieve de jugadores, tanto en el área maya como en Tula. Más aún, la descripción de lee estelas pipiles como pertenecientes a un frontón y por lo mismo en conexión con las creencias religiosas en relación con el juego de pelota, puede ampliarse hasta la zona arqueológica de El Tajín, Veracruz, donde las esquinas del juego de pelota se esculpi-

eron con ritos fúnebres relacionados con el culto del juego, ya que como sabemos por el *Popol Vuh*, aquél aparece en conexión con el dios de las subsuelos y de la muerte.

Ahora bien, nuestro radio de conocimientos en relación con el juego de pelota vino a aumentarlo la presencia de jugadores de pelota modelados en arcilla (Thompson, Note 25). Como quien esto escribe tenía ya noticia de otras dos piezas, el Sr. Thompson juzgó de interés se les conociera y reprodujera.

La primera figurilla precede de uno de los entierros de Jaina, Campeche, y se encuentra en el Museo Arqueológico de aquella ciudad. Fué descubierta por Miguel Ángel Fernández, sin que hasta ahora este arqueólogo mexicano nos haya descrito las condiciones del hallazgo. Sin embargo, el hecho de que en aquel santuario sembrado de sepulcros, aparezcan con tal abundancia las más preciosas representaciones escultóricas naturalistas, no sólo nos revela la importancia artística de su alfarería sino el que dichas representaciones realistas, con rasgos de individualización, pueden representar en las tumbas la réplica del muerto (sacerdote, cacique, jugador de pelota, guerrero, mujer noble, etc.) como un acompañante mágico. La figura de jugador a la que venimos refiriendo (Fig. 54.1a) no se encuentra, desgraciadamente, completa; está modelada en la arcilla arenosa y blanquizca de Jaina, sin bruñido, pero acabada con pintura aplicada al temple, como se observa en la rodillera que está coloreada de un precioso azul turquesa; el personaje lleva la

54.1. Figurilla maya de un jugador de pelota, Jaina, Campeche: **(a)** figurilla maya de un jugador de pelota, Jaina, Campeche; Museo Arqueológico, Etnográfico e Histórico de Campeche; **(b)** figurilla maya de un a jugador de pelota, Jaina, Campeche; Colección particular del Lic. Benito Coquet, México, D.F.

clásica deformación craneana de los mayas y viste los elementos distintivos de los jugadores, como el pesado cinturón sobre los que Thompson (1941b) ha llamado recientemente la atención.

La otra figurilla maya de un jugador de pelota (Fig. 54.1b) se encuentra en una colección particular de la ciudad de México, la del Lic. Benito Coquet, quien la adquirió en Mérida, donde se le informó su lugar de procedencia, la tantas veces mencionada Jaina, en Campeche. El jugador en este caso fué modelado en la posición clásica que vemos en

los relieves, por ejemplo, el del altar de Chinkultik, Chiapas, del Museo Nacional de México, ya que aparece arrondillado y llevando una pelota en la mano que, como en las estelas de Cotzumalhuapa, está grabada con un rostro humano. Como el ejemplar anteriormente descrito, pertenece indudablemente al período cerámico *Tepeu*. Lleva el clásico corselete, rodilleras, cinturón y guanteletes, pero el barro con que fué modelado se diferencia del ejemplar descrito en su color anaranjado y en la superior calidad del trabajo escultórico.

INSTITUTO DE INVESTIGACIONES ESTÉTICAS
MEXICO, D.F.

Un sello cilíndrico con barras y puntos

José García Payón

Encontrándome de paso en la ciudad de Jalapa, Veracruz, aproveché mi corta estancia para efectuar una visita a mi buen amigo al Sr. Ingeniero Cástulo Villaseñor, gran amigo de los arqueólogos y entusiasta coleccionador de nuestras antigüedades, que son la misma atención de siempre me mostró ufano sus últimas adquisiciones de piezas arqueológicas. Dicho señor es propietario de una bonita colección, de la que algunas piezas, las principales, son bien conocidas por los arqueólogos y del público amante de esta ciencia, por haber sido expuesta por mí, con la anuencia de su dueño, en el provisional Museo Arqueológico Veracruzano que con motivo de la reunión del VI Congreso Nacional de Historia se verificó en Jalapa durante el mes de septiembre de 1943, en el edificio de la Escuela Preparatoria.

Después de mostrarme varias piezas interesantes, especialmente figuritas sonrientes y otras, atraído mi atención un sello cilíndrico de barro rojo templado con arena de un tipo de decorado desconocido, y recordando el especial interés que el compañero y amigo Sr. Jorge Enciso tiene por estos artefactos, por estar preparando una monografía sobre los sellos de México prehispánica, pedí al Sr. Ingeniero me facilitara la pieza para obtener un dibujo; satisfecha mi petición, traje la pieza a mi oficina donde sin mayor atención la entregué al dibujante para que me sacara una copia exacta con el desarrollo completo del motivo ornamental.

Al recibir el dibujo y fijarme en él, me llamó la atención la singularidad de la pieza que claramente demuestra que se trata de un sello cilíndrico cuyo

motivo ornamental parece representar una fecha maya de la cultura de La Venta.

Suponiendo que se trata de una fecha maya, no se podía emprender el cálculo del mismo por otro número que no fuera el 10° baktun y girando la pieza se obtenía la siguiente correlación baktun 10; katun 19, tun 18, uinal 14 y kin 5, que según la correlación Goodman, Martínez Hernández, Thompson, corresponde a 13 Chicchan, 18 chen y al año de 1225.

Según los datos que tuvo la bondad de proporcionarme el Ing. Cástulo Villaseñor al obsequiarme la pieza, que a mi vez gustosamente cedo al Museo del Estado, fué encontrada en el patio de una casa de San Andrés Tuxtla, Veracruz.

Bajo el punto de vista arqueológico, esta pieza viene a demostrarnos que el uso de sellos tanto cilíndricos como planos era una costumbre bastante antigua y sostiene lo que pude corroborar en mis exploraciones en Zempoala, Veracruz, que el principio del empleo de estos artefactos fué anterior a la fundación de esta población arqueológica, que, como dije en otro escrito "Estado actual de las exploraciones de la Zona Arqueológica de Zempoala, Ver.," Archivo del I.N.A.H.) es contemporánea del primer período cholulteco.

Este hallazgo nos lleva a preguntar ¿por qué los indígenas pusieron esta fecha en un sello cilíndrico? Sabemos que éstos eran utilizados para estampar telas y posiblemente cerámicas, por lo tanto sirvió para recordar y conmemorar una fecha de significación por lo que parece que no fuera olvidada, fué

55.1. Sello cilíndrico con barras y puntos: (a) corte y desarrollo del sello cilíndrico; (b) fotografía en tamaño natural del sello cilíndrico con fecha maya.

posiblemente empleada en gran escala, estampándola en telas qua usaban.

Es de desearse que en futuros trabajos arqueológicos en la región de San Andrés Tuxtla, pudieran encontrarse mayores datos acerca de esta serie inicial.

Jalapa-Enríquez
Veracruz

[The possibility should not be overlooked that the designer of this seal borrowed the motif of bars and dots, as represented on stelae of La Venta culture in this area, purely as a decorative element. In that case the arrangement would have no chronological value. The general resemblance to an Initial Series is enhanced in the vertical position, but such an arrangement places the dots to the right of the bars, a practice taboo in Maya writing. On the other hand, far greater latitude was permitted in recording numbers in Zapotec writing, and the same may well be true of the inscriptions of La Venta style. It should also be remembered that by 10.19.18.14.5 the Maya no longer used the Initial Series. Editor.]

The Inscription on the Altar of Zoomorph O, Quirigua

J. Eric S. Thompson

The inscription on the altar of Zoomorph O, Quirigua, is very hard to decipher because of erosion, but also because of other difficulties. Carelessness on the part of the composers of the original text as well as unwonted urge for brevity, manifested in the suppression of month signs, make the translation far from easy. Morley (1938:5:185–196) has offered an interpretation, in which for the most part he expresses little confidence.

Messrs. Morris and Strömsvik made of this monument a cast which was subsequently presented by Carnegie Institution of Washington to the United States National Museum. Recently, through the kindness of Dr. Frank Setzler, photographs of the text were specially made from this cast, and presented to Carnegie Institution of Washington. These photographs, made in artificial light, a few blocks of glyphs to each plate, bring out many details (Figs. 56.1–5).

It is now abundantly clear that L4 is the month glyph. The coefficient is not a bar, as Morley had supposed, but a finger, as used occasionally by the Maya to express the number one. The nail of the finger is very clear. The month sign is the head variant of Kankin with the well-known *te* element above it. It is therefore clear that the Initial Series is 9.17.14.16.18 9 Etz'nab 1 Kankin. Morley had suspected that this was the date actually recorded, but because of his failure to identify the month sign, sad for other reasons, he placed three query marks after the reading.

Morley reads J1 as recording a moon age of 5 days. The photograph shows clearly that the element

which Morley took to be a numerical bar is a reversed count bracket. There is no coefficient. The moon age of this date is, therefore, 50 OD. Zoomorph G gives the moon age of 9.17.15.0.0 as 5C 23D. As the latter date is 22 days later than the former, the agreement is close. In fact, the combination of glyphs on Altar O may possibly mean 1D (just as C without coefficient is to be read as 1C). In that case the interval between the two lunar dates would be precisely 22 days.

In R1a there is a moon sign with a coefficient of 2. There is ample precedent at Yaxchilan, Piedras Negras, Balakbal, and Palenque for reading this as a distance number of 22 days. At R1b-Q2 there is recorded "5 Ahau 3 Muan, count of 5 tuns lacking," the only questionable matter being the glyph for Muan. Morley reads the first glyph as 5 Chuen and what I take to be 3 Muan, as 13 baktuns. This disagreement well illustrates the difficulties of this text. The arrangement is:

I.S.	9.17.14.16.16	9 Etz'nab 1 Kankin
R1a	1.2	Moon sign with coefficient of 2. Add
R1-Q2	9.17.15.0.0	5 Ahau 3 Muan. Count of 5 tuns lacking

There is a Secondary Series at S1a which appears to read 11–13 uinals, 7–9 kins. It may be followed at S1b by the posterior date indicator. At T1a there is a date 4 Chicchan or 4 Oc, 8 Uo or 8 Zip. Morley reads this as 4 Ahau 8 Cumku. For reasons which

56.1. Altar of Zoomorph O, Quirigua, text blocks A to L. (Courtesy of the U.S. National Museum.)

56.2. Altar of Zoomorph O, Quirigua, text blocks M to W. (Courtesy of the U.S. National Museum.)

will appear, I interpret this Calendar Round date as 4 Chicchan 8 Zip.

At U1a there is a glyph which Morley translates as "End of Katun 6," but which is surely the form of the kin sign consisting of a count bracket over one or two inverted Ahau's, and with the earth symbol at the bottom (cf. Glyph I1 on Stela C, Quirigua). This identification is confirmed by the presence in the adjacent block of the posterior date indicator. This misidentification leads Morley to place the subsequent dates some 200 years in the past. The coefficient looks best as 6, but must be 8, as we shall see.

At V1 there is a date 11-13 ? 16 Zip (conceivably Uo). This part of the text can best be rendered as follows:

R-1-Q2	9.17.15.0.0	5 Ahau 3 Muan. Count of 5 tuns lacking.
S1	11.7	Posterior date indicator. Should be anterior
	(9.17.14.6.13	12 Ben 16 Zip
T1	9.17.14.6.5	4 Chicchan 8 Zip
U1	8	Posterior date indicator
V1	9.17.14.6.13	12 Ben 16 Zip

At X1 5 Ahau is repeated, this time with the *ti* prefix, and is followed by what is probably a record of 5 tuns. A Secondary Series of 1 or 2 katuns, 9 or 7 tuns (7 is expressed as a bar, 2 dots and 2 crescents at S1), 6–8 uinals, and 7 kins occupies Y1, and is followed in X2 by an obliterated day sign with a coefficient which looks best as 11. At B'1a u.h. there is a katun sign with a coefficient which, at first glance, looks like a bar, but which is almost surely the finger representing the number one, for the indentation representing the second joint is visible on the lower edge. This must represent a distance number, for it is followed by the posterior date indicator. At C'1a u.h. there is a day sign with a coefficient of 4. It is a head in profile with a large round eye, and might be Cimi or Eb.

At B'2 there is another Secondary Series, and this seems to record 1 katun, 15 tuns, 11–13 uinals, and 1–2 kins. This, in turn, is followed in C'2 by a date which is almost without doubt 9 Lamat 1 Zec, as Morley has demonstrated. There is another distance number of 9.17.1 at D'b 1.h. and E'a u.h. and at E'1b u.h. and E'1a u.h. 9 Manik 5 Yaxkin stands forth with unexpected clarity.

This conglomeration of numbers and glyphs can best be arranged as follows:

V1	9.17.14.6.13	12 Ben 16 Zip
Y1	2.7.10.7	(written 2.7.8.7?)
X2	9.15.6.14.6	6 CimiB'1 (4 Zec)
B'1	1.(0.0.0)	Posterior date indicator
C'1a u.h.	9.16.6.14.6	4 Cimi (9 Cumhu)
C'1a 1.h.		Count of a katun?
B'2	1.5.11.2	(written 1.15.11 2 or 1)
C'2a	9.17.12.7.8	9 Lamat 1 Zec
D'1b-E'1a u.h.	4.17.1	(written 9.17.1)
E'1b u.h., a 1.h	9.17.7.8.7	9 Manik 5 Yaxkin

Unfortunately the distance numbers are such that whatever reconstruction is made, there must be errors. In that suggested above, one must assume the following mistakes: 8 uinals instead of 10 at Y1;

56.3. Altar of Zoomorph O, Quirigua, text blocks X to E'.
(Courtesy of the U.S. National Museum.)

15 tuns instead of 5 at B'2, and 9 tuns instead of 4 at E'1a (this last error is accepted also by Morley). One must, of course, avoid attributing errors to the Maya astronomer or sculptor until all possibilities have been exhausted along other lines. In this case, I think, there can be little doubt that the text has been correctly transcribed for the following reasons:

1. 6 Cimi 4 Zec was of great importance at Quirigua, and is repeated on several monuments, including Zoomorph G and the altar of Zoomorph P, the texts of which closely parallel that of the monument under discussion.
2. The glyph with coefficient of 19 which follows the assumed 6 Cimi 4 Zec at X2b, and which reappears immediately after the katun anniversary at C'1a, seems to be peculiarly associated with 6 Cimi 4 Zec. It is in all probability the same as that which follows that Calendar Round date at A13 on Stela E and at B12a on Stela F. Maudslay in both cases shows the coefficient as 18, but on the cast of Stela 8 there seem to be four dots and three bars. The prefix also is incorrectly drawn. On Stela F, on the other hand, the coefficient is clearly 18.
3. The recording of the katun anniversary of a date of the importance of 6 Cimi 4 Zec is in complete accord with Maya practice.
4. The texts at Quirigua, particularly of those monuments erected after 9.17.10.0.0, are carelessly written and abound with errors.

56.4. Altar of Zoomorph O, Quirigua, text blocks F' to J'4.
(Courtesy of the U.S. National Museum.)

It is impossible to connect the dates without making corrections. The above arrangement combines the most logical interpretation of the text with a minimal number of changes.

The most serious objection to the reading is that the coefficient of the day sign read as 6 Cimi looks very much like 11, and also looks like 11 on the Altar of Zoomorph P.

At the remaining dates on the monument I can only guess. At G'1b there appears to be a record of 4 Muluc, and the following distance number would take the count forward to 4 Cib, the details of which are fairly clear in the extra photo. After this may follow 12 Kan and at H'2 u.h. a distance number of 2 days, expressed by an inverted Ahau with coefficient of 2 and the terminal date 1 Cimi (interior resembles Cimi, an identification confirmed by calculation). At J'3a u.h. there appears to be a distance number of 14 kins. This is followed at J'4a u.h. by 3 or 2 *Ahau*. Calculation indicates that the coefficient should be 2. Next there comes a distance number written as 19 uinals 4 kins. As Morley has pointed out, 19 uinals is an impossibility. He suggests changing it to read 14 uinals; I take it as 18 uinals. At J'4b l.h. there is a very clear 2 Kan (Morley reads it as 1 Kan). The next recognizable glyphs form a distance number of 4 tuns, 2 uinals, and 15 kips. This is immediately followed by 1 or 2 Ahau, then what is apparently the posterior date indicator, and then a day sign with a coefficient of 2 and what is presumably a month sign (best as Muan or Xul) with a coefficient of 8. From somewhat similar examples on other monuments,

56.5. Altar of Zoomorph O, Quirigua,
text blocks I'5 to T'. (Courtesy of the U.S.
National Museum.)

56.6. Altar of Zoomorph O, Quirigua. Arrangement of text and suggested order of reading as far as J'6.

one can suppose that the distance number connects the two day signs.

There are a number of other glyphs with coefficients. Most of them are too eroded to decipher, but they might read 5 Ahau, 11 Ahau, 3 Ahau, and correspond to 9.17.15.0.0, 9.18.0.0.0, and 9.18.5.0.0.

The whole text, as far as it can be deciphered, appears to read as follows:

A1-L4	9.17.14.16.18	9 Etz'nab 1 Kankin. Moon 5C OD.
R1a	1.2	Moon sign
R1-Q2	9.17.15.0.0	5 Ahau 3 Muan. Count of 5 tuns lacking
S1	11.7	Posterior (for anterior) date indicator
	(9.17.14.6.13)	12 Ben 16 Zip
T1	9.17.14.6.5	4 Chicchan 8 Zip
U1	8	Inverted Ahau variant. Posterior D.I.
V1	9.17.14.6.13	12 Ben 16 Zip
Y1	2.7.10.7	(written 2.7.8.7?)
X2	9.15.6.14.6	6 Cimi (4 Zec). Day coef- ficient best as 11
B'1	1.(0.0.0)	Posterior D.I.
C'1a u.h.	9.16.6.14.6	4 Cimi (9 Cumhu)
C'1a l.h.		Count of a katun?
B'2	1.5.11.2	(written 1.15.11.2 or 1)
C'2a	9.17.12.7.8	9 Lamat 1 Zec
D'1b-E'1a u.h.	4.17.1	(written 9.17.1)
E'1b u.h.-a l.h.	9.17.7.8.7	9 Manik 5 Yaxkin
	(12.2)	
G'1b u.h.	(9.17.8.2.9)	4 Muluc (2 Pop)?
G'1 l.h.	12.7	
H'1b l.h.	(9.17.8.14.16)	4 Cib (9 Mac)?
	(8)	
F'2b u.h.	(9.17.8.15.4)	12 Kan (17 Mac)?
H'2a u.h.	2	
H'2b u.h.	(9.17.8.15.6)	1 Cimi (19 Mac)?
I'3a u.h.	14	?
I'4a u.h.	(9.17.8.16.0)	2 Ahau (13 Kankin)?
J'4	1.0.4	(written 19.4) Posterior D.I.
J'4 l.h.	(9.17.9.16.4)	2 Kan (12 Kankin)?
I'6b l.h.	(9.17.8.16.0)	2 Ahau (13 Kankin)?
I'6a, b, u.h.	4.2.15	
J'6a u.h.		Posterior D.I.
J'6b u.h.	(9.17.13.0.15)	2 Men (8 Ceh)?
K'2b l.h.	(9.17.15.0.0)	2 Ahau (3 Muan)?
M'1b l.h.	(9.18.0.0.0)	11 Ahau (18 Mac)?

May I again emphasize that the positions suggested for the dates from G'1 to the end of the text are no more than guesses. They are given principally as suggestions for future attempts to decipher this part of the text.

The decipherments of the first half of the text bring out a number of interesting points:

1. A head variant of the Initial Series Introductory Glyph corresponding to Kankin.
2. Afresh example of the use of the moon glyph with the value of 20.
3. One certain and one possible use of the inverted Ahau variant of the kin sign.
4. One certain and one probable use of the finger as a symbol for one.
5. Another example of the head variant for Kankin.
6. Two indubitable errors (wrong form of Glyph G; record of 19 uinals), and several probable errors in coefficients.
7. Strong evidence for another record of the important date 6 Cimi 4 Zec.
8. An almost certain katun anniversary of 6 Cimi 4 Zec.
9. A new moon age for a certain date.

Archaeological Discovery at Finca Arizona, Guatemala

Edwin M. Shook

Many important discoveries in the field of archaeology as well as in other sciences are made by nonprofessionals. So significant are some of these that one often hears wailing and gnashing of teeth by professionals who were not present for the unveiling and therefore were unable to record the exact circumstances surrounding the find. The excavations here reported were made by a layman, Sr. Juan Petrilli, but he, having kept in touch with the work of Carnegie Institution at Kaminaljuyu, realized the importance of careful observation. He had fortunately also been stimulated sufficiently to experiment in his own backyard. In fact, he almost destroyed his own house by excavating the mound supporting it. Archaeology is greatly in debt to Sr. Petrilli, his mother Sra. Rosa V. de Petrilli, and his sister Sra. Martha K. V. de Calvo for the care they exercised in the excavations at Finca Arizona, the preservation of the finds, and their generosity in making the entire collection of specimens available to the Carnegie Institution for study and publication.

Finca Arizona is a farm on the southern coastal plain of Guatemala, in the Department of Escuintla. It is 5 km north of the port of San Jose, and lies along the east side of the railroad from the port to Guatemala City. The altitude above sea level is 6.70 m. The flat terrain is broken only here and there by washes and streambeds. The nearest permanent river is the large Rio Maria Linda, 10 km to the east, although the bed of an intermittent stream passes through the farm. Freshwater may be obtained from wells no more than 5–6 m deep, even during the driest months.

The Pacific coastal plain of Guatemala, like most of Central America, has two distinct seasons: six months of severely dry weather from about October 15 to May 15, the remaining six months with considerable rainfall. The water table rises during the latter period, and sections of Finca Arizona become swampy. The heaviest precipitation occurs in September, and the farm and much of the coastal plain near the ocean is inundated. The 1942 records of nearby Port San Jose show a rainfall in that year of 78.3 inches, with 76.5 inches in the May 15–October 15 period, and only 1.8 inches during the entire dry season. The heaviest precipitation occurred in September with 22.0 inches or 28 percent of the year's total. Temperature is relatively high throughout the year, the hottest months being March, April, and May. The zone is subject to occasional high wind storms.

The soil in the neighborhood of San Jose is a fertile sandy loam formed from volcanic detritus which formerly supported a heavy growth of tropical timber, such as mahogany, Spanish cedar, balsam, and wild rubber. A large portion of the plain has now been deforested to permit extensive plantings of grass for cattle grazing. This is locally believed to have caused a change of climate, possibly in the past century, with increased temperatures and less rainfall. The shoreline was once much nearer the ancient settlement on Finca Arizona than it is today. In the memory, indeed, of the present inhabitants it has moved outward, because of the huge volume of sediment carried down from the steep slopes of the

57.1. Pottery from Finca Arizona, Guatemala: (a) brown-black bowl, strap handles (painting and description, Fig. 57.4a); (b) black bowl, labial flange with four scallops (painting and description, Fig. 57.4c); (c) Usulután tripod vessel with constricted orifice, gadrooned; base very slightly recurved (painting and description, Fig. 57.4b); (d) Usulután tetrapod vessel with constricted orifice, wide strap handles (painting and description, Fig. 57.4d); very faint gadrooning; base strongly recurved; (e) buff jar; slightly cracked buff slip with orange flushes, from interior base of neck over whole exterior; marks of finishing tool on slip very obvious; polishing cursorily done, leaving long, horizontal dull streaks where tool failed to touch; three sets of two preslip, shallowly grooved, concentric crescents; slightly recurved base unworn; (f) red-on-brown jar, recurved base (painting and description, Fig. 57.4f); (g) orange jar, anthropomorphic; base not successfully flattened as jar sets out of plumb where placed on an even surface (painting and description, Fig. 57.4g). (Scale = 1/4.)

57.2. Pottery from Finca Arizona, Guatemala: (a) black tetrapod cylindrical vessel; base very slightly recurved; feet oval in section (painting and description, Fig. 57.4e); (b) incised and relief decoration of *a* (see also Fig. 57.6b); (c) incised and relief decoration of *f* (see also Fig. 57.6d); (d) orange cylindrical vessel (painting and description, Fig. 57.6a); shallow grooved line on averted rim; upper part of wall pushed out to form a broad, rounded, horizontal molding with appliquéd elements (see painting); (e) dark red-on-red cylindrical vessel (painting and description, Fig. 57.6b; incised and relief decoration, *b* of this figure); (f) dark red-on-red cylindrical vessel (painting and description, Fig. 57.6d; incised and relief decoration, *c* of this figure); (g) dark red-on-red cylindrical vessel (painting and description, Fig. 57.6c); (h) Usulután cylindrical vessel, stuccoed (painting and description, Fig. 57.6e); (i) dark red-on-red cylindrical vessel; the only one of the dark red-on-red pieces without relief decoration (for description, see caption of Fig. 57.6b). (Scale = 1/4.)

57.3 (*facing page*). Pottery from Finca Arizona, Guatemala: (a) Usulután bowl (painting and description, Fig. 57.5a); (b) orange bowl; two shallow, preslip, encircling grooves on exterior below rim; fairly well-polished, uncracked, brownish orange, all over slip; horizontal strokes of tool used in preliminary smoothing left shallow, elongated, depressions which were passed over by the polishing tool and remain as narrow, dull streaks; buff cloud on exterior (Usulután?); base unworn; (c) Usulután vessel, small (painting and description, Fig. 57.5c); base slightly recurved; (d) Usulután bowl; base thickened to produce flat bearing surface; two shallow, preslip, encircling grooves under outcurve of rim; well-polished, very slightly cracked, orange slip over interior and halfway down on exterior; lower part of exterior and base, orange with black fire clouds; finishing-tool marks visible; sets of four vertical, parallel straight lines on interior and exterior walls (cf. Fig. 57.5a); wavy, and therefore more typical of Usulután technique, lines on interior bottom; base unworn; (e) Usulután bowl (painting and description, Fig. 57.5b); two preslip, shallow, encircling grooves on exterior of standing part of wall; (f) Usulután bowl; grooving, as in *e*, is polished; cracked, orange, all-over slip; marks of finishing tool visible; eight sets of five parallel, vertical, straight buff lines on exterior; apparently same on interior, but almost invisible; base very little worn; (g) Usulután bowl; shallow, preslip encircling groove and eleven crescentic grooves on thickened and flatly everted rim (see reduced top view); note annular indentation near outer edge of base; well-polished, considerably cracked, orange, allover slip; sets of four parallel, vertical, straight buff lines on interior and exterior wall (cf. Fig. 5a), wavy lines on interior bottom; buff blotches on exterior (cf. Fig. 5a); base unworn; (h) black bowl; broad labial flange with four equally spaced scallops; upper surface with encircling line and looping line coarsely incised after slipping (see reduced top view); polishing of the uncracked chocolate-brown to black slip, which covers all surfaces, done after incising; black parts of slip iridescent in places; traces of red in incising may be remains of a sizing coat under a now vanished coat of stucco (see captions of Figs. 57.4, 2; 57.6e), but probably pigment rubbed into incising (see caption of Fig. 57.4e); base unworn; (i) buff bowl with restricted orifice; encircling preslip groove just below orifice on exterior; three appliquéd crescentic fillets and a boss on shoulder (see reduced top view); indifferently polished, very slightly cracked, buff slip covers entire vessel except appliquéd elements; periphery of a dark fire-cloud on exterior wall is flushed to orange; recurved base worn; (j) Usulután vessel with restricted orifice; exterior encircled by two preslip, shallow grooves and a broad shallow undulant groove; in the spaces formed by the latter are four bosses and four U-shaped appliquéd fillets in alternating order; cracked, orange, all-over slip, polished on exterior and just over lip on interior; buff blotches on exterior and six sets of five parallel buff lines running from lip to edge of base; interior buff with orange blotches; slightly recurved base a little worn. k. Usulután whistling vessel (painting and description, Fig. 57.5a). (Scale = 1/4.)

volcanic chain about 60 km inland. Evidence that this has been going on for a long time was recently brought to light near San Jose when, during leveling for an airport, an old beach was found to lie about 1 km inland. Abundant archaeological remains were encountered, indicating a village site of a cultural horizon postdating that of the specimens described in this report. Thus it seems probable that in this vicinity the most ancient sites will be found 3 or more kilometers back from the coast, and more recent remains as one moves towards the sea within the 3 km zone. There are also many very large archaeological sites on the broad plain stretching back to the foothills of the volcanoes, giving evidence that the area was heavily populated in aboriginal times.

A. V. Kidder and I visited Finca Arizona in company with Sr. Juan Petrilli on April 12, 1944, and inspected the mound from which came the majority of the material here reported. We examined two groups of mounds and Sr. Petrilli reports others. One group lies in and around the Petrilli residence on both sides of the railroad tracks, the main house atop a large mound. Part of the latter was cut off to form the house foundation; later Sr. Petrilli made a large pit under his dining room (more or less in the mounds center) and found, about 1.25 m below the house floor, a fine figurine head (Fig. 57.4n). The fill

of the mound consists of homogeneous loamy brown earth without stones and with very few potsherds.

Another larger and more compact group lies 2 km southeast of the finca house on the east side of the dry streambed passing through the farm about 4 km inland. It consists of at least four mounds irregularly placed around a plaza. The south unit, Mound I, is the largest, roughly 40 m square at the base and, before excavation, about 10 m in height. Sr. Petrilli began his excavations with a trench from the east towards the mound center about 3 m below the top. Nothing was encountered in the outer layer except featureless fine brown soil containing a few pottery fragments and two "Archaic" type figurines (Fig. 57.7l). This was undoubtedly the weathered remnant of the latest increment of the pyramid, which may have supported a structure of perishable material. Near the mound's center and 2 m below its top there was found a wide, well-preserved floor supporting a small double platform. In order to expose this, Sr. Petrilli removed most of the overlying earth. Skeletons of two young children, perhaps babies, lay on the floor outside the northwest and southwest corners of the platform. No mortuary furniture accompanied these burials.

Further excavation disclosed three stages of structural activity. The broad floor had formed the

top of the pyramid on which later was built a rectangular platform, and still later a smaller platform was superimposed on the first.

In the primary stage, the floor forming the pyramid top had been well tamped and surfaced with a thin layer of clay painted red. On this was erected a plain rectangular platform with vertical sides, 65 cm in height. Several extended burials of adults

with many pottery vessels were placed within the platform. The latter was made of well-packed, fine brown sandy soil; and plastered with a thin coat of clay painted yellow on the sides and red on top. A smaller platform of the same material was built on the one just described, leaving a narrow 4.5 cm wide terrace. This upper platform, 90 cm in height, was also surfaced with clay and also painted yellow on

57.4. Pottery from Finca Arizona, Guatemala: **(a)** brown-black bowl, strap handles (silhouette, Fig. 57.1, a); well-polished, uncracked, all-over slip; color ranges from reddish brown through chocolate-brown to deep black; postslip thin-line incising; base considerably worn; **(b)** Usulután tripod vessel with constricted orifice, gadrooned (silhouette and reduced top view showing angularity of gadroons, Fig. 57.1c); polished, uncracked, all-over, orange slip; curvilinear decoration of interior and exterior in buff to buff-brown; feet slightly worn; traces of yellow buff stucco below orifice; possibly once covered whole exterior except base; **(c)** black bowl, labial flange (silhouette and reduced top view showing scalloping of flange, Fig. 57.1b); well-polished, uncracked, deep black, all-over slip; stucco from 1 cm within orifice to and over edge of flange; stucco decoration involved three operations: (1) application of thin, brownish red sizing coat; (2) laying-on of relatively thick coat of white stucco; (3) application of bright rose-red paint or very thin stucco; base unworn; **(d)** Usulután tetrapod vessel with constricted orifice (silhouette and half-drawing to show very faint gadrooning (Fig. 57.1d); highly polished, uncracked, all-over, orange slip; decoration in yellowish buff; traces of stucco that apparently extended from just within orifice to point of greatest diameter: thin, dull purple sizing coat; thicker layer of white stucco; medium thin outer coat of brilliant pink; feet moderately worn; **(e)** black tetrapod cylindrical vessel (silhouette, Fig. 57.2a); brownish black, considerably crackled, all-over slip; well-polished even on interior and base; rounded molding encircles top of wall; two deeply grooved, preslip lines at base of wall; coarse, post-slip incising: single line just below molding and two opposed panels; incising tool left broad, V-shaped lines with very ragged edges; work apparently done at leather-hard stage; red pigment subsequently rubbed into lines; **(f)** red-on-brown jar (silhouette, Fig. 57.1f); fairly well-polished (but with elongated dull streaks missed by finishing tool), slightly crackled slip from interior base of neck over entire exterior; dark red painted decoration on upper body and base of neck outlined by thin; postslip lines incised with round-pointed tool, apparently at leather-hard stage; in places, pressure of the tool not sufficient to cut through slip, merely pressing it into the shallow line; base unworn; **(g)** orange jar, anthropomorphic (silhouette, Fig. 57.1e); conventional human face on neck, plain fillets representing arms on upper part of vessel's body, farther down two bosses indicating legs or feet; the nose-mouth element and ear bosses appliquéd; eyes punched into vessel's neck with flat, blunt-ended tool producing, in each eye, two rectangular, horizontal depressions; face area painted black; fairly well-polished, orange or orange-brown, uncracked slip from interior base of neck over whole (?) exterior; certain lighter orange areas may indicate use of Usulután technique, but there are no definite lines; stucco from a little below point of greatest diameter to and over lip: thin, dark red sizing coat; relatively thick background layer of blue-gray stucco over which was applied a geometric decoration in turquoise blue, yellow, and possibly other colored stuccos, each color having been laid on as a separate operation and sections of the blue-gray background having been left exposed to form part of the now badly damaged design, which is accordingly both in relief and color (cf. Kidder and Shepard, note 35); the black-painted face area appears not to have been stuccoed. (Scale = 1/4.)

the sides and red on top. Within it were interred the skeletons of six adults with a wealth of pottery vessels and jade ornaments.

Twenty-five complete pottery vessels, one marble bowl, and 34 fine jade specimens were found in the two platforms. All are described in the captions of the illustrations. No separation of the material from the two levels was made in the field, and no attempt has been made to do so in the report. The pottery obviously belongs to a single ceramic phase, and it is doubtful if much time elapsed between the construction of the two platforms.

The specimens were in unusually excellent condition. Many vessels were unbroken; others although broken were repairable. Sr. Cesar Tejeda F. performed this tedious task; his brother, Sr. Antonio Tejeda F. made the drawings and paintings here reproduced. The latter, which like all Sr. Tejeda's work, are both beautiful and meticulously accurate, unfortunately cannot be shown in color. They have been deposited, with all his other paintings of Mesoamerican pottery, in the Peabody Museum of Harvard University.

DISCUSSION

In the nature of wares, vessel shapes, finish, and methods of decoration, the pottery recovered by Sr. Petrilli on Finca Arizona is closely akin to that of the Miraflores phase, the oldest ceramic complex thus far recognized at the archaeological site of Kaminaljuyu in the outskirts of Guatemala City or, for that matter, anywhere in the highlands. This statement will have, for the present, to be taken on-trust, for until the Miraflores material has been published it would be useless to detail the many resemblances between the two groups. The only striking difference lies in the greater elaborateness of certain of the Finca Arizona pieces, a difference probably to be explained by the fact that they formed part of the grave furniture of persons who, because of their burial in specially constructed platforms at the summit of a large mound, and, because of the number and richness of the offerings of pottery and jade that accompanied them, were obviously persons of high standing, whereas the Miraflores mortuary pottery of Kaminaljuyu is represented

57.5 (*facing page, top*). Pottery from Finca Arizona, Guatemala: **(a)** Usulután bowl (silhouette, Fig. 57.3a); deep, preslip, encircling groove on exterior just below lip; polished, slightly crackled, all-over orange slip; four sets of four parallel, vertical, straight, buff lines running downward from lip on exterior and interior; lighter buff clouds on exterior; base worn; **(b)** Usulután bowl (silhouette, Fig. 57.3e); two preslip encircling grooves on exterior of standing part of wall; well-polished, crackled, all-over orange slip; sets of four very faint, parallel, vertical, straight lines on exterior and interior; base unworn; **(c)** Usulután vessel, small (silhouette, Fig. 57.3c); shallow encircling groove on lip and a series of broader grooves encircling body from outcurve of rim to edge of flat base, all preslip; two small, flat, opposite lugs; uncrackled, all-over, orange slip, polished over entire exterior and on interior to base of rim; inner surface of rim and whole interior buff; on exterior narrow buff lines and splotches; base slightly worn; **(d)** Usulután whistling vessel (silhouette, Fig. 57.3k); heavy strap-handle; monkey head and neck, which contain whistle, made separately and welded into top of forward jar; arms, neckband, and biblike ornament appliquéd; interior of neck of rear vessel and whole exterior of specimen except under side of handle and the monkey head covered with slightly crackled, highly polished orange slip; decoration in narrow buff lines; several buff clouds; base worn. (Scale = 1/2.)

57.6 (*facing page, bottom*). Pottery from Finca Arizona, Guatemala: **(a)** orange cylindrical vessel (silhouette, Fig. 57.2d); upper part of wall pushed out to form a broad, rounded, horizontal molding; somewhat crackled, all-over orange slip, puffy clouds on interior (Usulután?); slip on exterior, rim, and interior to upper edge of molding well-polished; interior unpolished; two preslip encircling grooves below molding and two at base of wall; on molding, two opposite bosses and two opposite pairs of crescents, appliquéd before slipping; traces of plaster-like material suggest that vessel may have been stuccoed; base unworn; **(b)** dark red-on-red cylindrical vessel (silhouette, Fig. 57.2e); incised and relief decoration, Fig. 57.2b); this and the three vessels shown at *c* and *d* of this figure and *i* of Figure 57.2 have the following features in common: large size; averted rim with thickened lip; vertical wall curving gently to flat base, the latter, in *c* and Figure 57.2l, very faintly recurved, perhaps due to warping; single rounded, horizontal molding just below outcurve of rim (for remarkable uniformity of shape, see silhouettes, Fig. 57.2e–g, i); all four were completely covered with somewhat crackled red slip; then a secondary coat of darker shade was applied to the interior and exterior of the averted rim above the level of the molding, the same color being used to produce bold designs on the exterior below the molding; the exterior of the vessels, except the base, was well-polished, as was the interior of the rim; a few cursive strokes of the polishing tool were sometimes given to the interior wall and base; finally, the darker red designs were outlined by fine, shallow, post slip, groove-incised lines done with a round pointed tool; the base of this and the three other pieces in the same category are slightly worn; **(c)** dark red-on-red cylindrical vessel, the largest of the group (silhouette, Fig. 57.2g); the decoration in darker red appears most plainly on this specimen; the conventional monkey figure, like that of *b*, was modeled from appliquéd lumps and fillets of clay before the vessels were slipped; the figures themselves were neither slipped nor polished; **(d)** dark red-on-red cylindrical vessel the finest of this series (silhouette, Fig. 57.2f); incised and relief decoration, Fig. 57.2c); the stylized face strongly suggests that of the rain god Tlaloc; if correctly identified, this would appear to be the earliest known representation of that deity; the outer half of the appliquéd fillets forming the two drooping curved elements and the inverted V over the eyes was slipped and polished; their inner half and the area they enclose were left unclipped and unpolished; **(e)** Usulután cylindrical vessel, polychrome stucco (silhouette, Fig. 57.2h); set of three rounded moldings below averted rim emphasized by four grooved lines (concealed by stucco in the painting); the faces, forehead, puffed-out cheeks, and chin were given high, rounded relief by pressing out the wall from the interior (see silhouette); the ears, coffee-bean eyes, nose, and mouth were appliquéd; the exterior of the wall was worked into twenty-two vertical, flat-surfaced panels; well-polished, uncrackled orange slip, over exterior of wall, rim, and part way down on interior; decoration, largely covered by stucco, in buff to brown crosshatching; exterior base and lower part of interior, buff unpolished; secondary decoration in colored stucco in vertical bands corresponding to the twenty-two vertical panels; apparently, the entire surface to be stuccoed was given a thin sizing coat, and then all but four panels received a thick layer of stucco mixed to the desired color; the four exceptional panels, the area surrounding the face and covering the moldings, and the exterior and edge of the rim were nest of precooked stucco but were treated with white stucco and then painted bright red; order of colors, beginning with the light panel below the faces left side and continuing clockwise: yellow, deep red, bright red, turquoise, greenish buff (probably originally green), purple, yellow, bright red, turquoise, greenish buff, purple, yellow, bright red, turquoise, greenish buff, purple, yellow, bright red, turquoise, greenish buff, deep red, purple; the sequence of application could be made out from overlapping of the stucco: first the four purple panels, then four greenish buff, four yellow, four white (afterward painted bright red), four turquoise, lastly the deep reds, which, it will be noticed, were the two short panels below either side of the face; the final operation was the coating of the central part of the face with yellow and of the surrounding area and the rim with white stucco painted bright red; a face of this peculiar puffy-cheeked, slant-eyed type appears in a squat Usulután jar, probably from Kaminaljuyu, in the Guatemala National Museum, and another on a brown-black specimen from near San Cristobal, Dept. of Totonicapan. (Scale = 1/4.)

57.7 (*facing page*). Pottery from Finca Arizona, Guatemala: **(a)** marble tripod bowl; expertly wrought, contours true, very thin wall (3 mm) and base (2 mm); corrosion has rendered granular the doubtless originally smooth surfaces, leaving coarse crystals in relief; examples of similar labial-flanged form have been found at Kaminaljuyu in Miraflores deposits but of other sorts of stone; this seems to be the earliest example of such work in marble so far discovered; small double-cups of alabaster occur at Kaminaljuyu in tombs of the post-Miraflores Esperanza phase; **(b)** tubular jade bead; fine-quality, brilliant dark-green stone with white streaks; **(c)** jade pendant, one of an identical pair, evidently cut from the same piece of deep green, white-mottled stone; **(d)** tubular jade bead, flaring end, one of a pair; dark green, white mottling; **(e)** celt-shaped object, jade (?); highly polished, edge sharp; dark blue-green stone similar to that of a small anthropomorphic figure from an Esperanza phase tomb at Kaminaljuyu and of certain La Venta specimens; **(f, g)** jade beads, two of four; poor quality, light-colored stone. Specimen *e* is one of three that were perforated from one side, apparently with the same hollow drill, as their slightly conical bores are identical in shape and size. The fourth, *f*, was similarly drilled, but with a larger tool that did not quite penetrate the bead. The remaining section was broken through, leaving an irregular edge about the opening (see its section). **(h)** Rectangular jade pendant of pale blue-green stone; symmetrical in form and highly polished; two pairs of small biconical perforations for suspension; **(i)** large tubular, carved jade bead; in section, rectangular with rounded corners; opaque gray-green; not highly polished; red pigment rubbed into lines of decoration; **(j)** jade earplug flare, one of an identical pair; opaque gray white to green, mottled with brighter green; medium polish; obvious marks of sawing tool on exterior of stem; this specimen and its mate evidently cut from the same piece of stone; **(k)** jade earplug flare, one of an identical pair; opaque gray white mottled with clear dark green, well-polished; this pair also from a single piece of stone. All four of these flares are of a type found in Esperanza phase tombs at Kaminaljuyu; the latter, however, usually have one or two perforations in the side of the stem. Note: of the above jades, *c* and *e* were found with one of the burials; all the others with another. In the latter lot were also (1) 16 small highly polished beads of bright green stone, 1 cm in average diameter, 0.5–0.9 cm thick, 12 biconically perforated, 4 from one side only; (2) a tubular, dull green jade bead, 2.7 cm long, 0.8 cm in diameter, highly polished, biconical perforation; (3) a tubular bead of highly polished, micaceous, blue-green stone, 1.9 cm long, 0.5 cm in diameter, perforation from one end, a tiny red stone bead, lodged in the base at one end. **(l)** Head of pottery figurine, unslipped, gray with orange flushes; hollow, hand-modeled; animal head; eye represented, as was that of the face on the anthropomorphic jar (Fig. 57. 4g), by two rectangular, horizontal depressions made with a flat, blunt-pointed tool, but in this case the pupil, not rendered on the jar, was indicated by a single gash made with a sharp tool; from fill above burials in Mound I; **(m)** head of pottery figurine, unslipped brown ware; solid, hand-modeled; triple-punch eye made with wedge-shaped, sharp pointed tool; fill of Mound I; **(n)** head of pottery figurine, cinnamon, apparently slipped; solid, hand-modeled; eye formed in appliqué filled by two lateral applications on the side and one central punch with the end of a tapering, round-shafted, blunt, pointed tool; from mound under Sr. Petrilli's residence. (Scale = 1/4.)

by no more than a half-dozen very ordinary pieces from two simple, open-earth interments, evidently of commoners.

I am convinced that the Finca Arizona pottery is of Miraflores date. The Miraflores phase of Kaminaljuyu is unquestionably a manifestation of the so-called Archaic stage of Mesoamerican development. It has for some time been realized that, ceramically at least, the Archaic cultures were far from primitive and now the Finca Arizona mounds supplement the

evidence of the pyramid at Cuicuilco in the Valley of Mexico that the Archaic peoples were not only sophisticated potters, but that they had already achieved governmental and religious organizations sufficiently mature to render them capable of producing large ceremonial structures. This adds to the certainty that the Archaic must be the result of a long period of development and renders it even more puzzling that no pre-Archaic remains have yet been identified in Mesoamerica.

The Initial and Supplementary Series of Stela 5 at Altar de Sacrificios, Guatemala

Sylvanus G. Morley

I first saw Stela 5 at Altar de Sacrificios in the spring of 1914, when the drawing of its corresponding Initial Series shown in Figure 58.1 was made. Beyer had not then discovered the meaning of the variable central element of the Initial Series introducing glyph, and there was no reason for doubting the reading that I then suggested: 9.10.1.13.18 6 Eznab 16 Ceh.

In 1931 Beyer (1931) announced his decipherment of the variable central element of the Initial Series introducing glyph as "the month-sign indicator." This formula, the accuracy of which is now universally recognized by Maya epigraphers, showed that the above reading was incorrect. The terminal date is Ceh, whereas the variable central element of the Initial Series introducing glyph (Fig. 58.1a) is very clearly the moon sign, which corresponds to the month Chen.

In the spring of 1944 I visited Altar de Sacrificios a second time and obtained a photograph of this inscription (Fig. 58.1b). This appears to warrant the following identifications:

A1-B2. The variable central element of the Initial Series introducing glyph is surely, as originally drawn by me in 1914, the moon sign, thus indicating that the corresponding month in the Initial Series terminal date must be Chen.

A3. 9 *baktuns*. The coefficient is certain as 9, although a fracture line runs vertically through the four dots.

A4. 10 *katuns*. The coefficient is certain as 10, although the same fracture line continues down between the upper halves of the two bars before turning off toward the right.

A5. 11 *tuns*. The single numerical dot and the lower of the two non-numerical, flanking crescents show clearly. Furthermore there is dust-enough space between the foregoing and the badly eroded period glyph to the right for two thin numerical bars of exactly the same width as those in the uinal coefficient immediately below. Indeed the uinal coefficient, which is surely 12, is of exactly the same width, i.e., that of a line of dots and two bars, as the tun coefficient of 11, i.e., one dot flanked by two crescents and followed by two bars. It was my original misreading of the tun coefficient as 1 which led to my error in deciphering this date.

A6. 12 *uinals*. The coefficient is certain as 12, although the corresponding period glyph is effaced.

A7. 17 *kins*. The coefficient is practically certain as 17, the only alternative being 18.

A8. 6, 7, 8, 9, or 10 *Caban*, or *Eznab*. The coefficient here is surely over 5 and under 11. As the kin coefficient is 17 or 18 the day sign must have been Caban or Eznab. In 1914 I observed in my notes: "the coefficient of the day (A8), or what I believe to be the day here, is surely between 6 and 10 (inclusive)."

58.1. Stela 5, Altar de Sacrificios: (a) drawing of the Initial Series made in 1914; (b) photograph of front taken in 1944.

A9. Effaced. Probably Glyph G5 or G6 of the Supplementary Series, depending on the kin coefficient, but more probably the former than the latter.

A10. Glyph F of the Supplementary Series. Identification is certain.

A11. Glyph 3D of the Supplementary Series. The coefficient here is best as 3, although 1 and 2 are possible readings. The corresponding moon age recorded is either 3, 2, or 1 day in that order of probability.

A12. Glyph 5C of the Supplementary Series. Coefficient and C variant of the moon sign are certain.

B3. Not clear, but probably not Glyph X5 or X6 of the Supplementary Series, one or other of the two forms of Glyph X required by a coefficient of 5 in Glyph C.

C3. Not clear, but probably not Glyph B of the Supplementary Series.

B4. Not clear, but probably not Glyph A9 or A10 of the Supplementary Series.

Gathering these data together, we have the following reading of this Initial and Supplementary Series by inspection: 9.10.11.121? 6 Caban (5 Chen) G5. F.—. 3D. 5C.—.—.—. in which the first dash indicates that Glyph E of the Supplementary Series is not required here and the second, third, and fourth dashes that Glyphs X5 or X6, B and Ag or A10 apparently are suppressed in this particular inscription. It should be noted in passing that out of the eight other Supplementary Series known here at Altar de Sacrificios, Glyph B is suppressed in all eight of them and Glyph X in all but one; but that Glyph A, on the other hand appears in all eight.

According to Roys’s revised table of lunar ages, the moon age corresponding to the Initial Series 9.10.11.12.17 is 2.9 days, a very close agreement with the moon age actually recorded at A11, i.e. 1, 2, or 3 days.

The moon ages of all dates in Baktun 9 with a katin coefficient of 10, and tun coefficients of 1, 6, 11, and 16, which also fall in the month Chen, were calculated. Of these 80 dates, 78 were eliminated because of disagreement with the recorded moon age or because they fell outside the limits set for the coefficients of the kin or day signs. The two dates which alone survived the test are those already reached:

Initial Series		
9.10.11.12.17	6 Caban 5 Chen	G5?
9.10.11.12.18	7 Eznab 6 Chen	G6

Supplementary Series		
F.—3D.5C.—.—.—		
F.—3D.5C.—.—.—		

There are many points of agreement in both of the above readings and not a single disagreement.

Analyzing these two dates with their corresponding moon ages, we find that:

1. Both fall in the month Chen as required by the Initial Series introducing glyph.
2. Both have tun coefficients of 11, the best provisional reading of the tun coefficient in A5, by inspection.
3. Both have uinal coefficients of 12, by far the best provisional reading of the uinal coefficient in AE, by inspection.
4. The first has a kin coefficient of 17, by far the best provisional reading of the kin coefficient in A7, by inspection, and the second has a kin coefficient of 18, the only other possible value of the kin coefficient in A7.
5. Both have day coefficients, 6 and 7 respectively, which fall within the range of the five possible day coefficients, 6, 7, 8, 9 or 10, as fixed by the day in A8, by inspection.
6. The first has a calculated moon age of 2.9 days, only one tenth of a day earlier than the recorded moon age of 3 days in all, and the second has a calculated moon age of 3.9 days, only nine-tenths of a day later than the recorded moon age of 3 days in A11.

As between these two possibilities the first is much the more probable: first, because the kin coefficient in A7 is much better as 17 than 18; and second, because the calculated moon age of no. 6 (2.9 days) is nearly a day nearer the recorded moon age (3 days) in All than the calculated moon age (3.9 days) of no. 7.

It is unfortunate that A9 is too far gone to identify, for it occupies the position of Glyph G of the Supplementary Series and had it been preserved, it would have confirmed either of the above readings; i.e. G5 if the kin coefficient had been 17, or G6 if it had been 18.

Concerning the contemporaneous date of Stela 5 at Altar de Sacrificios it would seem to have been either 9.10.10.0.0 13 Ahau 18 Kankin or 9.10.15.0.0 6 Ahau 13 Mac. In favor of the later date is the fact that this monument formerly stood on the north side of the plaza of Group I in line with, and some 20 m east of, Stela 4, the dedicatory date of which is surely 9.10.10.0.0 13 Ahau 18 Kankin. Stela 5, like Stela 4, is carved on its front only, the sculptured panel being all glyphic, that is, having no figures.

Stela 6, on the other hand, stood a little behind and between Stelae 4 and 5, at a slightly higher level. Maler (1901–1903) reports it as unsculptured and I was unable to find any traces of former carving on it, either in 1914 or 1944, although he regards it as not at

all improbable that originally it may have been sculptured. If so, because of its more important position in having stood, not only at a higher level but also between the other two flanking stelae, it may well have been dedicated on the relatively more important period ending 9.11.0.0.0 12 Ahau 8Ceh, Stela 4 standing below and to its left having been dedicated in 9.10.10.0.0 13 Ahau 18 Kankin and Stela 5 below and in a balancing position to its right having been dedicated in 9.10.15.0.0 6 Ahau 13 Mac. If this arrangement and these decipherments are correct, these three monuments would have commemorated three successive hotuns of the Long Count: 9.10.10.0.0 13 Ahau 18 Kankin (Stela 4), 9.10.15.0.0 6 Ahau 13 Mac (Stela 5), and 9.11.0.0.0 12 Ahau 8Ceh (Stela 6). If this interpretation of its contemporaneous date should

be correct, then the Initial Series of Stela 5 is only 3.5.3 (463 days) earlier than its dedicatory date.

On the other hand, if Stela 6 always had been unsculptured, then it seems more probable that Stela 5 originally had the same dedicatory date as Stela 4, i.e. 9.10.10.0.0 13 Ahau 18 Kankin.

Against this latter hypothesis is the fact that its corresponding Initial Series, 9.10.11.12.17 6 Caban 5 Chen, would then be 1.12.17 (617 days) later than its corresponding dedicatory date, a very rare condition indeed in the *Corpus Inscriptionum Mayarum*, though not unique. In favor of this second hypothesis as to the contemporaneous date is the fact that the day 13 Ahau seems to be recorded at C7, though whether the corresponding month part "18 Kankin" was formerly to be found at B8 cannot now be determined.

Mausolea in Central Veracruz

Jose García Payón

For some time I have been interested in some curious small structures, first reported by Isidro A. Gondra (1836). Sr. Gondra's account was based on some clippings from newspapers of Veracruz which described the discovery of some pre-Colombian ruins in the Mizantla region, and on a verbal account by Sr. Mariano Jaimes who visited the nearby Ranchos de Monte Real that same year.

In 1844 Col. Ignacio Iberri published in *Museo Mexicano* (3:21–24) a report on these ruins, together with a map. In 1864 Sr. Gondra, having obtained fuller details and utilizing the colonel's report, published a second article (1836). He added the information that "el nicho era abovedado y en el hallaron esqueletos humanos en postura agachada," Various contradictions in these accounts caused much confusion as noted by Bancroft (1874–1876:4:449).

In 1889 Herman Strebel (1885–1889:2:15–16) noted that in the middle of the virgin forest in the archaeological zone of Tacahuite, near Vega de la Torre, he found numerous structures of stone and mortar. They resembled houses, were a yard long at the base, had a step, a niche in the middle, and a sloping roof (Fig. 59.4b). He adds that below one of these structures were human remains. After discussing whether these buildings could be of Spanish origin, he concludes by supposing that they were chapels for saints or sepulchral monuments, and are in every way similar to those reported by Sr. Gondra at Monte Real.

It is strange that these two students who wrote on the same subject, but twenty-five years apart, had not actually seen the structures they describe. In my

unpublished work "El Templo de las Caritas de la zona arqueologica de Zempoala" I said that Strebel's lack of veracity in certain parts of his study is explicable if one takes into account the fact that he was never in Mexico, but obtained most of his information from the Mexican conchologist, Sra. Estefania Sales de Broner, who made numerous discoveries in the area between the Actopan and Nautla rivers. She also placed him in contact with Señores Ramon Fuentes and Mardonio Yañez, who supplied him with the information he required and at his written behest made several archaeological trips in that region, then largely uninhabited. Later Dr. Strebel was efficiently aided by Dr. Rudolf Krause who came to Mexico to collaborate in this study, and who was a guest of Sra. Sales de Broner at her various haciendas in Veracruz.

The Comisión Científica Exploradora de Zempoala de 1893 found numerous small constructions which they called *boveditas* on the hill named Maria Andrea near the sea, and in the direction of Laguna Verde. Francisco del Paso y Troncoso (1897:2:282–283) describes them in the following words: "Todas tienen la apariencia de casas aztecas, estan edificadas con laminas de laja y blanqueadas con argamasa . . . todas tienen la particularidad comun de ester vueltas con las puertas hacia el mar, estando por este motivo orientadas hacia el Oriente. Estan cerradas por todos lados y solamente tienen una entrada . . . que las da la apariencia de nachos."

The author considers them to be prehispanic and supposes that there were idols in the niches.

59.1. Tombs at Quiahuixtlan.

He suggests that they were shrines where the rising sun, as it emerged from the sea, was worshipped, or where the remains of children sacrificed to the rain gods were placed (Galindo y Villa 1912). Dr. Walter Krickberg (1933) considered these reports to be too conflicting and vague to be utilized.

During my last season's work at Zempoala my attention was particularly attracted by a small circular construction with a rectangular front (Fig. 59.3a). There are remains of the upright surface on the north side. The whole is very similar to the Ehec atl building at that site.

After a careful investigation I was able to corroborate that this was a tomb, for I found that the center was hollow, and originally had been covered with a floor. There were lateral walls covered with mortar. The remains of these pointed to the existence of a small rectangular enclosure with north-south axis. The floor had been broken by grave-looters some years ago.

With this discovery in mind, I decided to seek some of these small structures in the area from which they were reported by the earlier writers. Accordingly Professor Jose Luis Melgarejo Vivanco, who refers to these structures in his work *Totonacapan* (1943:119), his brother, and I visited the old center of Quiahuixtlan. This city, to which Cortes and his men passed after their brief stay in Zempoala, and which is described by Bernal Diaz del Castillo, is situated in the woods around the slopes of the Cerro de Quiahuixtlan. On the summit of the hill, which serves as a lookout point, are the remains of stucco floors and a cistern shaped like a half-egg,

59.2. Map of small plaza at Quiahuixtlan: (1) buttress-like support; (2) large tombs; (3) lines of tombs; (4) artificial fill.

59.3. Plans and sections of tombs: (a) circular tomb, Zempoala, 1:50; (b) Tomb of Quiahuixtlan, 1:20.

59.4. Various structures: (a) Tomb at Texuc (drawn by J. L. Melgarejo V.); (b) plans of various structures after (1) Strebel; (2) Hrdlicka; (3) Toledano; and (4) Gondra.

and stuccoed on the interior. In the northeast side of the hill, and almost at the foot of the rocky summit, is what I call the cemetery of Quiahuixtlan (Fig. 59.2). It is formed of various lines of mausolea, all looted and all black with smoke (the land had been burned for milpa a few days before). These are in the shape of small temples varying in height from 1 m to 1.6 m (Figs. 59.1; 59.3b). Each one contains a small chamber which I believe served as a depository for offerings by relatives of the deceased. Below the floor is an area which held the body of the deceased in flexed position. This was square and 55 cm across, or circular with variable dimensions.

Before each mausoleum at Quiahuixtlan there stands a statue in the round which represents an animal. The material is mortar and the subjects embrace turtle, monkey, jaguar, frog, serpent, etc. This find suggests the possibility of a form of totemic.

The lines of mausolea are stepped owing to the fact that they are situated on the south side of the little plaza which in turn merges with the slope of the hill. The north side of this plaza is built up with a buttress-like support of rough stone which extends across a small valley. On the east side of the small plaza there are three somewhat larger structures, 2.75–3.24 m across the front and with narrow passages between. Heights can not at present be estimated, for only the bases remain. All are in bad shape, the southernmost being the least damaged. The center one alone may not have been looted. The bases are similar to more of the religious structures of Temporal, except that southeast of the structure of Ehecatl.

On the west of the little plaza there are traces of a rectangular construction about 10 m wide across the front. To the east of this, but on a lower level, there are slight traces of another line of small mausoleum

facing the three large ones. Dominating the whole, on the highest part of the slope of the hill, there is another line of mausoleum with the façades on the north side. It would seem that there is no definite scheme of orientation. The majority, like that of Temporal, are oriented to the north (Mictlampa, region of the dead), but the three largest face west, and others the east.

In the course of our short visit it was impossible to determine whether these mausolea are pre-Colombian or date from the earliest years of the conquest, as Strebel believed. In favor of the second theory is the proximity of this site to the early Spanish port and garrison town of Villa Rica. The natives may have seen Spanish mausolea there (the commandant of the garrison lost his life) and adapted them to their own use.

Professor Melgarejo V. found at Texuc (El Bernalillo) one of these small structures in the form of a native hut (Fig. 59.4a). The cavity below the floor was circular.

The known distribution of this type of structure appears to be confined to central Veracruz from Zempoala north to Tacahuite, near Vega de la Torre. The western boundary is at present in the Mizantla region. The actual sites from which they have been reported are: Zempoala, San Isidro, Cerro Tres Picos, Arroyo Mariano, Bernalillo (Texuc), Quiahuixtlan, Cerro Cercado, Boca Andrea (Paso y Troncoso calls this Maria Andrea), Moro, Tacahuite, and Monte Real.

Professor Melgarejo found seven floors in the mausoleum of Texuc; six in one at Quiahuixtlan. They vary in thickness from 1 to 9 cm. He believes that each new level represents a period of fifty-

two years. Counting backwards from the new fire ceremony of 1519, he reaches A.D. 1155 and A.D. 1207 as the respective dates for the erection of these two structures. I am not inclined to accept this interpretation.

Excavation of the structure at Zempoala produced only one sherd. This is of colonial manufacture and is a fragment of a tripod bowl with small solid feet of teat shape. The bottom was striated before firing. It is made of a reddish sandy clay, well baked, and covered with a dark yellow glaze. This detail which demonstrates the postconquest origin of these tombs, must be accepted with caution. One cannot overlook the possibility that the sherd accidentally fell in when the floor was broken by grave-robbers.

With regard to comparative data, I would call attention to the report of Ales Hrdlicka (1912) in which the sections of a tomb at Teotihuacan are illustrated (Fig. 59.4b). Hrdlicka says the cavity was shaped like a large broad jar. The superposition of cement floors led him to conjecture that there had been a structure above.

At Poza Larga, in the former district of Tetela, Lic. Vicente Lombardo Toledano (1931) found at the foot of a pyramid a tomb made of clay blocks. Inside was a vessel containing human bones. The section which he publishes (Fig. 59.4b) resembles strikingly the lower part of the Quiahuixtlan tombs, although the upper part is missing. In the archaeological zone of Paxilila-Morelos, in the Mizantla region, I have found many tomes, all looted, but none resembles the type under discussion.

The definite resolution of the question of the age of these mausolea must await their careful excavation.

VERACRUZ

Archaeological Material from the Club Internacional, El Salvador

Stanley H. Boggs

In 1939, during construction of the present building of the Club Internacional in the center of the city of San Salvador, workmen excavating the basement discovered a deposit of prehistoric objects associated with a stratum of volcanic ash. This material, according to Sr. Don Jose Maria Duran, architect and building contractor in charge of the work, was found mixed together in a very small area. No burials or structures of pre-Columbian age have been reported within at least 1 km of the finds.

Many visitors to San Salvador have viewed some of the specimens discussed in the present *Note*, and several of the polychrome bowls have been commented upon by Longyear and others. The following account is the first, I believe, to attempt a fairly detailed annotation of all the finds together with their place of discovery. The importance of the Club collection arises from the facts that one specific stratum of volcanic ash contained all the specimens, and that a number of easily recognizable, possibly datable, pottery wares were represented.

STRATIGRAPHY

Sr. Duran has informed me that the layers of soil penetrated by his workmen at the point of discovery of the archaeological objects, a spot approximately 20 m north of the 2a Calle Oriente and 35 m east of the 2a Avenida Sur, were as follows: (1) 2.5 m of volcanic ash with much loose (recent?) humus mixed especially into the upper portion, overlying (2) alternating thin layers of sand and gravel totaling 0.75 m

in thickness, which rested on (3) hard, white volcanic ash of unknown depth.

The specimens hereinafter described, now on exhibition at the Club (except for one shown in Figs. 60.2g, 60.3k, owned by Sr. Duran), were found at the base of, but clearly within, the uppermost stratum.

SPECIMENS

MONOCHROMES

Coarse gray clay, unpainted and unslipped

Figs. 60.1 a, 60.3e. Jug or jar with two vertical loop handles, ovate body and rounded base. Surface rough and light gray. Black firing clouds.

Fig. 60.3p. Half of a small bowl with thickened rim and flattened base. Surface: interior polished with clear striations (of stone polishing?); exterior smoothed but unpolished. Very dark gray.

DICHROMES

a. Red-on-gray cantaros or jars

Figs. 60.1b; 60.3b. Compressed-globular body with rounded base. Flaring neck connected to upper curve of body by two vertical loop handles. Lip thinned and sharp. Surface unslipped, light gray, and well smoothed. Red painted design is confined to the upper half of body curve, between handles, and to one side of the neck. Broad-outlined areas between the handles with fineline filling-elements are characteristic of design. On neck of vessel appears a schematic (anthropomorphic?) face, formed by appliqued bits of clay.

Figs. 60.1c; 60.3a. In nearly all respects, this is simply a larger version of the foregoing specimen. The loop handles, however, are confined entirely to the upper curve of the body, the painted lines are not sharply defined (smoothed before paint was dry?), and apparently no filling design was painted in the trapezoidally outlined area between the handles. The stylized face on the neck of the jar is painted red, its ear elements are pierced and the eyes are separated from the muzzle. The polished surface is considerably darker than that of the vessel last described.

Fig. 60.3g. Neck only of a jar almost certainly of the same style as the above. The polished surface bears three red squares painted on dark, unslipped gray clay.

b. Ring-and-dot jars.

Figs. 60.1e; 60.3l. Globular body with marked shoulder, rounded base, flaring rim with characteristic profile. Smooth surface. Lower half of body covered with smeared, whitish wash. Upper half, including neck and rim, painted with thick, dark red, typically crackled in firing. On the red areas are painted rows of, and groups of, three white circles. This white circle motif is repeated on the flat portion of the rim. Paste is rather coarse, reddish brown, friable.

Figs. 60.1f; 60.3c. Globular body with vertically flattened side walls, pronounced shoulder, rounded base. Rim resembles that of foregoing. Surface lightly polished. Except for the unpainted, unslipped basal area, surface is painted with a simple design in red on buff slip. Paste rather coarse, red, friable.

c. Light red-on-orange-buff.

Figs. 60.1d; 60.3j. Sherd of simple silhouette bowl with round lip. Extending a short distance below rim on exterior is a slightly concave band, apparently caused by a special thinning of the bowl walls as rim was approached. Possibly original bowl possessed restricted orifice. Surface polished lightly and slipped light orange-buff, both interior and exterior. On upper third of exterior, a light red design involving simple geometric elements, some possibly derived from glyphs.

POLYCHROMES

a. Red, black and orange "glyphic" bowls.

Figs. 60.2a; 60.3o. Simple silhouette, sharp rim, rounded base. Surface badly eroded. Red, black and orange design painted on exterior only. Decoration is, characteristically, in two horizontal bands. This specimen shows two types of "glyphs" outlined in red and orange filled, repeated twice, the pairs

alternating. In lower band appear four black, linear monkeys in profile, separated one from the other by crosshatched red lines.

Figs. 60.2e; 60.3g. Double curve profile, flat base and sharp lip. The well-smoothed surface is orange slipped, interior and exterior. Red and black painted design appears on exterior only in two horizontal bands which are separated one from the other by broad red and thin black lines. Upper band bears four black outlined "glyph" elements with red filling separated by black X's; the lower band shows a black scalloped or wave motif.

b. "Copador" bowls.

Figs. 60.2j; 60.3f. Fragmentary simple silhouette bowl with flat base, round lip. Highly polished surface with specular hematite red and black on orange slip design, interior and exterior. Horizontal red lines divide exterior decoration into two horizontal bands which cover the entire surface. Characteristically, in this specimen, the upper band contains a pair of "glyphs" repeated three times, red outlined and orange filled. Lower band shows a ceremonially dressed human figure (probably two on complete vessel), semi-reclining on knees and elbows, his upraised hands and feet apparently supporting the upper, "glyphic" band. Figure outlined in black and filled with red. Interior of bowl dominated by an unusual, possibly "glyphic," figure (Fig. 60.21), red outlined, repeated three times. Paste very fine. Paste color shades from light buff at surface to dark gray in center.

Figs. 60.2d, n; 60.3h. Fragmentary simple silhouette bowl very similar in form, color, and design to the foregoing, but slightly larger. Chief difference between the two is that interior and exterior upper-band decorative motifs of the present vessel are similar, whereas those of that described above differ from each other.

Fig. 60.3i. One shred of bowl with slight double curve and low-round lip. Surface badly eroded. Very little of the painted decoration remains. Apparently vessel was orange slipped, polished, and bore a "glyphic" design in secular hematite red and black, on exterior only, in the upper band. Lower band design too fragmentary to permit determination of motifs.

c. "Copador" vase

Figs. 60.2k; 60.3m. Fragmentary flat-based with slightly flaring rim and low-round lip. Surface very smooth, and slipped orange on exterior only. Decoration consists of two, black painted, horizontal bands showing, as principal features, ceremonially dressed, seated human figures. Some "glyphic" ele-

60.1. Pottery from the Club Internacional, San Salvador.

ments seem to have been included in the lower band, to judge from the fragment remaining. Rest of surface painted with specular hematite red. Paste appears untempered, white, and has chalky feel.

d. Rapid or "shorthand" style

Figs. 60.2h; 60.3n. Flat-based, simple silhouette bowl with nearly flat lip and slight bulge on exterior below rim. Smooth surface slipped light buff. Exterior design consists of poorly, perhaps hastily, painted motifs in red, black and orange in three horizontal bands. Characteristically, red and black were employed to outline the figures, orange to fill them. In this example, the decorative elements are unusually difficult to determine, but on the basis of comparisons with better painted specimens, it seems likely to me that the uppermost band bears highly stylized feathers, the lowermost band, geometrized animal heads (pisotes?), repeated four times. Interior design destroyed almost completely. Paste rather coarse, well fired, but surface soft.

Figs. 60.1h; 60.3s. Bowl with annular base, flaring rim, sharp lip, and nearly flat bottom. Surface is polished and, for this style of pottery, hard. Decoration consists of black and dark orange motifs painted on light orange slip, interior and exterior. Exterior design includes simple geometric, orange figures in rectangular areas outlined in black. Interior design badly stained, but side walls seem to have carried geometric elements similar to those of the exterior, whereas the bottom was decorated with an anthropomorphic figure dressed in ceremonial attire. Paste coarse and well fired.

Figs. 60.2f; 60.3u. Tetrapod bowl with shallow-rounded bottom, sharp basal flange, flaring rim, and round lip. The round peg-feet contain rattles. Surface almost powder soft at the present time, but on the few parts retaining original finish it appears to have been polished. The all-over slip seems to have been light orange over white. Black and orange-red decoration was painted on both interior and exterior of the bowl but is now almost entirely gone. Remaining

60.2. Objects from the Club Internacional, San Salvador: (a, d–k) pottery vessels and fragments (approximately 1/3); (b) peccary (?) tusk; (c) figurine head (approximately 1/3); (l) design element from interior of *j* (approximately 1/2), specular hematite red outline, orange filling; (m) design element from exterior of *f* (1/1), black (solid) and red-orange (hachured); (n) design elements from exterior of *d* (approximately 1/2), black (solid) and specular hematite red (fine stippling) outlines, orange (open stippling) filling.

60.3. Profiles of pottery vessels. (Scale = 1/3.)

designs include black out-lined geometric figures filled with orange-red. Paste dark red, fine-grained, and hard-fired.

Figs. 60.1g; 60.3l. Tripod vase with two bat-head lugs, shallow-rounded base and flat rim. Hollow slab feet with very thin side walls. Vessel walls very uneven in thickness but surface is well smoothed and slipped with orange-over-white. Red, orange and black design on exterior consists of stylized bats with outstretched wings, separated by two complex, badly eroded figures. Framing these major elements are horizontal bands about the base and upper quarter of the vessel. Figures are generally outlined in black, with red or orange filling. Although the surface is soft and easily eroded, the paste is fine, red, and well fired.

Figs. 60.2g; 60.3k. Tripod vase with flat base and rim, hollow slab feet, and two low, horizontal ridges on exterior surface which break decoration into three bands. Surface fairly soft but well finished and in fine condition. Painted designs of the uppermost and lowermost horizontal bands include following colors based on Ridgway's nomenclature: red (Morocco Red to Mahogany Red), brown (Mars Brown), black, and orange (Mars Orange to Flesh Ocher) on light orange slip (Pinkish Buff to Pale Ochraceous Salmon). Between these painted areas occurs an encircling, incised textile design, covered with white paint after incising. Interior of vessel bears one dark red, solid, horizontal band near rim and, below, orange color painted almost to the base to cover a broad-line, lost-color design in the original light orange slip. Paste rather coarse, reddish, hard-fired.

e. Purple polychrome

Figs. 60.2i; 60.3. Tetrapod bowl with rounded base, flaring rim, round lip, and solid feet. Surface hard and polished. Painted decoration consists of simple geometric figures in red and dark purple on cream slip. The rather peculiar but characteristic form of the supports is derived from animal-effigy heads, generally pisotes, to judge from comparable vessels of this style found at other sites. Paste coarse, well fired, dark red.

Fig. 60.3r. Two fragments of a bowl, very similar in most respects to the foregoing but with annular base. A fragment of design on the interior bottom of this bowl shows stylized feather motifs.

FIGURINE HEAD

Fig. 60.2c. Crudely finished, solid pottery head, broken from some larger object. Modeled from coarse, gray clay. Face painted red.

ANIMAL TUSK

Fig. 60.2b. Probably the tusk of a *tunco de monte* or a peccary.

COMMENTS

The area of San Salvador has been blanketed periodically in the past by successive falls of white volcanic ash, and various collections of prehistoric objects have been recovered from what is apparently the most recent of these strata. Certain materials were undoubtedly intrusive and refer to a later date than the ash fall (Boggs 1944). Others, such as those now being considered, must refer to the time of the fall itself.

Inasmuch as postconquest alterations of the latest ash layer by man, animals, erosion, and the like invite confusion in determining stratigraphical position of finds said to be from that level, it is best to consider only those deposits known, or believed, to be undisturbed.

Nonintrusive, undisturbed deposits are characterized by lack of association with mounds or burials, by the facts that many of the objects are fragmentary and that no apparent care was taken in arranging them. Those known to me occurred near the base of the latest ash, whereas intrusive deposits were found at almost any elevation in that stratum. It does not seem likely that such nonintrusive deposits represent formal caches. Many individual specimens from different finds of this category are closely comparable to one another, and the combinations of types within such groupings of objects are sufficiently similar that one may believe their deposition to have occurred at approximately the same time.

Obviously, the importance of relating easily identifiable pottery types to distinctive strata of volcanic ash derives from the possibility of dating both pottery and ash; so that whenever, in other parts of the geographical zone investigated, previously unidentified and undated human remains are brought to light from the same ash layers, or accompanying the known, dated pottery, some chronology at least may be set up. Up to the present time, no thorough investigation has been conducted of the extent or composition of any ash layer in El Salvador, although recent studies by the Salvadoran Instituto Tecnológico emphasize the value of such research to archaeologists.

The chief aids to dating the latest central Salvadoran ash horizon have been prehistoric pottery objects from the Club Internacional; Tazumal, Campana-San Andres and Hacienda Tula, some of which are relatable to various dated wares from Copan and Guatemala.

At Tazumal, the grave complex represented by Tombs 1-4 and included ring-and-dot jars, copador, rapid or shorthand, and purple polychromes. Both purple polychrome and red-on-gray cantaro sherds were discovered to be associated in a late ash stratum of the Hacienda Tula, probably having been deposited at the same time as the Club specimens (Longyear 1944). At Campana-San Andres, copador, rapid or shorthand, and red, black and orange "glyphic" polychrome sherds are found together in the same building level. Therefore, we have some reason to believe that the Club association of pottery types is more or less typical of a central and western Salvadoran ceramic complex at a certain period of prehistory.

Copador polychromes, when present among the finds, furnish the most reliable assistance in dating western Salvadoran pottery of late 9th cycle Maya styles, for their position in time of 9.12.5.0.0 to/or 9.16.5.0.0 is fairly well assured by the fact that they were found in caches below Stelae I and J and under the altar of Stela J at Copan. The term copador, suggested to me by A. V. Kidder, implies briefly what is now thought to be the principal area of distribution of the style, that is, the Copan region, southwestern Honduras, and El Salvador west of the lower Lempa River. Not enough is yet known about this polychrome to define even a majority of its stylistic peculiarities, to say nothing of the variety of forms and, probably, pastes. To date, copador refers mainly to a distinctive style of painted pottery on which human figures and stylized Maya glyphs or glyph elements are very commonly depicted, as well as to the use of specular hematite paint in the decoration. The usual color combination is red and black on orange slip, but at times vessels decorated in the style are unslipped, at others five or more colors are employed.

Whether the rapid or shorthand polychrome style is Maya, or is the handiwork of some other

ethnic group, cannot yet be proved, though available evidence tends to support a Maya relationship. Stylistically, examples from the Club Internacional and from Tazumal tombs show some resemblances to vessels described and figured by Strong, Kidder, and Paul (1938), especially to "Upper Ulua" and "Upper Yojoa" types. As is the case with most varieties of southern Maya pottery, rapid or shorthand polychromes cannot yet be satisfactorily defined; they thus remain no more than easily recognizable styles, or a complex of styles, in which the painting was done with a very distinctive combination of colors.

Red, black, and orange "glyphic" bowls may be slightly earlier in time of development than either copador or rapid or shorthand styles, to judge from discoveries at Copan (Longyear 1952) and Tazumal. In neither site; however, can they have much antedated the latter types and may have been more or less parallel developments. It is worthwhile to note that 3.n many "glyphic" designs, specular hematite red paint was employed, and the color combinations are similar to those of copador.

Very little information exists regarding distribution or stylistic range of either ring-and-dot jars or purple polychrome. Lothrop (1927:192), notes discovery of an example of the former in Mound 36 at Copan, but aside from this I am unaware of its discovery outside El Salvador. The easy identification of this dichrome, as well as of purple polychrome, should make both styles of considerable value in dating future finds with which they are unearthed.

In summary, the Club Internacional pottery, from comparisons with groupings of vessels brought to light at nearby sites, may be considered one fairly typical ceramic association in western El Salvador of the late 9th cycle. Therefore, the volcanic ash in which these specimens were discovered probably refers to the same period of time.

Drawings and painting are by Antonio Tejeda F.

Some Uses of Tobacco among the Maya

J. Eric S. Thompson

These scant jottings on "the weed" have lain among my notes for many years. I have not attempted to improve the mixture by seeking more gleanings to blend with it, but offer it more or less as garnered without any pretense that it adequately covers the subject. Information on the use of tobacco among the Maya of the sixteenth century is extraordinarily scarce. Bishop Landa has a single and rather obscure reference to ceremonial blowing of smoke in an initiation ceremony for children, but it is not even certain that that was tobacco smoke.

The chaplain, Juan Diaz, of the Grijalva expedition writes that at Cozumel the natives presented Grijalva and some of his men with "some canes about a palm long which, on being burnt, gave off a delicate odor." Cane (*cana*) is the term generally used by early chroniclers to describe the aromatic cigars used by the Mexicans.

A much later, but very interesting, account of cigars and their manufacture appears in the *Registro Yucateco* (1:349–350). The article is entitled "Cocom" and is signed "un curioso." *Cocom* is the name of an unidentified tuberous plant with yellow flowers. The tubers of this were cut in narrow strips, which were carbonized on a very hot *comal* (griddle). The material was then pulverized, and placed in a gourd or vessel. *Atole de camote* (sweet potato gruel) and a little honey were added, so that the mixture formed a thick paste. The maker of the cigar then took leaves of the zapote (*Achras zapota* L.), or, were he a resident of Chichanha, leaves of the allspice (*Pimenta officinalis* Lindl.), and split them lengthwise. Each

half-leaf was next rolled on a small, spindle-shaped stick, about as thick as a turkey quill, and tied with henequen thread. The surface was then coated with the cocom paste, except for about an inch at the thinner end, which was to serve as the mouthpiece. The stick was pulled out, after the whole had been dried in the sun, and tobacco, of the kind regularly used in making cigars, was inserted in its place. The end was doubled over to prevent the tobacco spilling, and the cigar was then ready for enjoyment.

One is reminded by this description of the perfumed canes of tobacco and liquidambar, smoked by the Aztec. In the highlands of Guatemala, according to Fuentes y Guzman (1932–1933), guayava leaves were used to wrap cigars. On the other hand, the Lacandons used cigarros of pottery which were curiously painted (Villagutierre y Sotomayor 1933, Bk. 5, Ch. 6). From the use of the word *cigarro* one can perhaps infer that these were tubular pipes.

Cigars are mentioned in the *Popol Vuh*. Xbalamque and Hun Ahpu are required to pass a night in the cave of darkness, and to emerge next morning with their cigars and pine torches still alight, after having kept them burning all night. The young men extinguish their cigars and put fireflies on the ends so as to make the people of Xibalba believe that they are still alight. This incident must have formed part of the body of holy tradition shared by all Maya groups, for there is an indirect reference to it in Yucatecan literature. Among the riddles put to candidates for chieftainship, as preserved in the Book of Chilam Balam of Chumayel (Roys 1933:97), occurs the fol-

lowing: "Son, bring me the firefly of the night. Its odor shall pass to the north and to the west . . . What he asks for is a smoking tube filled with tobacco," As Roys has suggested, these riddles were designed to elicit information as to whether a candidate had a sufficient fund of the esoteric knowledge necessary for his future office. A thorough acquaintance with Maya tradition and mythology clearly was one of the required subjects.

Among the present-day Yucatec the Chacs (rain gods) are said to be very fond of smoking, and comets are said to be their glowing cigars (Tozzer 1907:155, 156). One sincerely hopes that the Maya informant meant to tell Dr. Tozzer that shooting stars represented the cigars, for had they smoked only on those rare occasions when a comet is visible, they would have been very far from chain smokers.

Snuff mixed with lime was, and still is, favored by some Maya groups. Frederick Starr (1902) reports that the Tzeltal chew powdered green tobacco mixed with lime and chili. The mixture is dipped from a calabash with a little sticklike spatula) and is chewed or sucked "to strengthen the teeth." Starr illustrates the long tapering gourd which serves as the receptacle. In his book *In Indian Mexico* he adds the information that the mixture was called *mai*. *Mai* is a general word for tobacco in several Maya languages and dialects. It is defined in the Motul dictionary as tobacco powder, made by rubbing tobacco leaves between the fingers. In Kekchi the word is applied to the leaf. It has been suggested that the synonymous term *mai*, twenty, originated from the custom of tying tobacco leaves in bundles of twenty. The Motul dictionary also lists the word *bux* with the meaning of gourds used for holding tobacco.

This habit of chewing lime and tobacco is prevalent also among the Tzotzil, according to information given me by the schoolmaster of Zinacantan, Chiapas, and formerly existed among the Jacalteca (La Farge and Byers 1931:123). Indeed, the custom is widespread in Middle America. It has been reported from Oaxaca and from the region of Texcoco (*Pomar relación*; see also Ruiz de Alarcon 1900, Trat. 1, ch. 4). The custom was also prevalent among the Jicaque of Honduras. According to Ramon de Anguiano (1798) green tobacco leaves and lime, obtained from the small fresh-water shells commonly called *hutes*, were chewed by the Jicaque as a malaria preventative.

It seems highly probable that the chewing of tobacco and lime in Middle America is a transmutation of the Andean custom of chewing coca leaves with lime. The latter practice extended as far north as Nicaragua (Oviedo y Valdes 1851-1855, Bk. 6, Ch. 20). Thence it is but a short step to Honduras. In both

cases the lime, I believe, has a chemical effect on the stimulant. In both cases the mixture is stored in a narrow-necked gourds and dipped by means of a spatula.

A quite different use of tobacco is reported by that charming fraud, Thomas Gage (1677). He describes the making of *chicha* (beverage of fermented cane syrup) by highland Maya, presumably Pokoman, and imparts the information that tobacco leaves and roots were added to strengthen the brew. He notes that sometimes a toad was inserted for the same purpose.

Green tobacco is an element in many Maya remedies (Roys 1931), but I know of no use by the lowland Maya of tobacco-chewing or swallowing to produce the right conditions for divination. This is perhaps because I have not combed the literature with sufficient diligence, for it is highly probable that the custom was prevalent among them, as among the highland Maya (Fuentes y Guzman 1932-1933, Pt. 1, Bk. 12, Ch. 3), the Mexicans to the north, and in Colombia. Tobacco is used, however, by Chorti medicine men in a form of divination (Wisdom 1940:344). The diviner chews tobacco, and rubs the saliva on his right leg. In answer to questions the spirit dwelling in the calf of his right leg gives a twitch of the calf muscles as an affirmative answer; no twitching is a negative reply.

Archaeological evidence for the use of tobacco among the Maya is somewhat unsatisfactory. The personage sculptured on the right of the entrance to the sanctuary of the Temple of the Cross, Palenque, appears to be smoking a tubular pipe, perhaps in a ceremony analogous to the blowing of tobacco smoke to the four world directions by North American Indians. On page 79b of the Madrid Codex a *tonalpoualli* (260-day sacred almanac) is divided into fifths, and each of these has three subdivisions. These three subdivisions are illustrated by pictures of Gods B, A, and E. Each god lies on his back on the earth (indicated by Caban symbols), and has what appears to be a cigar in his mouth. These are tubular but taper somewhat toward the end held in the mouth. Each has a black rim at the other end. A cascade of black dots, which might well represent smoke or sparks, is just beyond the end. Our present understanding of the accompanying glyphs gives no clue as to the meaning of the scenes.

Excavations have produced a few pottery fragments which might have formed parts of pipes, but in some cases there is a strong possibility that they are parts of brazier handles. An elbow pipe, said to have come from Palenque, is discussed by Douglass (1889), but one must accept that attribution with the greatest reserve. Elbow pipes of that general type are

common enough in the Valley of Mexico, but, so far as I know, none has ever been found under archaeological conditions in the Maya area. Elbow pipes are used, however; by the present-day Chorti, together with tubular pipes. They are of wood.

The negative evidence of archaeology and the positive evidence of literature suggest that in pre-Colombian times the Maya made little use of pottery pipes (the Lacandon pipes may be exceptional),

but smoked their cigars wrapped in leaves or used containers of perishable materials. The tobacco and lime chewing quite possibly reached the Maya as an attenuated substitute for coca and lime, perhaps not long before the conquest. It might have been one of those elements, such as the hammock, bitter manioc, and the pineapple, which appear to have reached the borders of the Maya realm shortly before the Spanish conquest.

Observations on Altar Sites in the Quiche Region, Guatemala

Elsie McDougall

In February 1928, while a guest in the Protestant mission house in Santo Tomas Chichicastenango, I was told of a *brujeria* where Indians worshipped. A group of town picnickers had discovered it on the wooded summit of a hill, about 1 km west of the town. Starting before midmorning of March 1, Harry Grainger, the missionary, a young townswoman, and I visited the hilltop. We took the road west from the convent part of the imposing sixteenth-century Catholic church, where Indians were praying and burning incense in a forge like altar at the foot of the steps and on the terrace at the threshold of the church. The road passes the accumulation of adobe brick, white-washed houses owned by rural Indians. These houses, with rooms opening on an inner court, are occupied only when members of the family unit are in town for trade, for duties related to civil administration and to the maintenance of the two churches (the second is that of El Calvario, on the west side of the plaza, fronting the larger "parochial"), and for religious ceremonies, including those conducted by the resident "foreign" (Catholic) priest. We ascended the hill by a branch footpath through cleared land, partly under cultivation. A few unkempt young Indian girls, pasturing all black as well as white sheep, ran away swiftly at sight of strangers.

Locating the place of worship in the woods, largely of pines, was facilitated by the sound of fervent prayer. An Indian was praying on behalf of a seated man (Fig. 62.2). The former was recognizable as a professional officiant, one or more of whom

are commonly to be seen in the two churches, performing the required ceremonies at floor altars of temporary construction. On these are placed cloth-wrapped bundles containing seeds, coins, candles, copal incense, quantities of flower petals, and aguardiente. This last is poured around the candles by the professional prayer man. There is a close relationship between the floor altars in the churches and the altar on the hilltop.

The holy place in the woods actually consists of two altars. The main stone of the larger altar is an image, undoubtedly pre-Spanish, and at the time I first saw it, was recumbent and lacking the head. The arms are folded across its breast, and a trophy head, with hair pendant, is attached to the front of a wide-fold girdle (Fig. 62.1a). There are also crosses, in both low and full relief, one or two old mortars, club heads, a large ball or sphere incised and painted with irregularly crossing lines, chipped and broken manos, and flat-based boulders with holes in the center. All these are of stone. Old stone boulders with holes are placed in front of side altars in the town churches to hold the ceremonial staves of *cofradia alcaldes* while the *cofrades* are engaged elsewhere. Except for the crosses the stones are probably of pre-Colombian manufacture.

Maize cob husks, the discarded wrappings of four or five small cakes of copal incense, littered the foreground. In front, the ground was carpeted with pine needles: Some newly cut boughs of pine, similar to the ones partly covering the smaller altar (Fig. 62.3a), were at the foot of a tree. Copal incense,

arranged in small piles as it is unwrapped, was first burned, and as it smoked, a row of small candles before the altar were lighted. The well-articulated, fervent prayers were in Quiche; the word "Señor" in pleading tone was frequently interpolated. The informant, a young townswoman familiar with Quiche, told me that the prayers were for good crops, the health of the family, and malediction of enemies. As foreign intruders, we were specifically mentioned. Scowled glances on the part of the seated man also made us aware that we were unwelcome, and so our stay was brief.

Visiting the place of worship two days later, again in midmorning, I found that pine boughs lightly covered the altar. Hot ash of copal and the warmth of the stone image on removal of the covering testified to a recent ceremony. On chalking the incised lines of the stone figure to bring out the relief, I was handicapped by the constant slipping of the chalk on the surface, made sticky by what was probably a combination of carbon grease and *aguardiente*.

I returned to Chichicastenango late in the afternoon of December 19 of the same year. The town was already thronged for the fiesta of the patron saint, officially commencing the following day. I had promised Franz Termer, who had already arrived in Chichicastenango for the celebrations, to show him the altar, and as I was not too certain of the path, I decided to try and find the altar that evening so as not to fail as a guide the next day. As I approached the woods at dusk, I saw a column of smoke rising above the treetops, evidence that a ceremony was in progress. The cracking of twigs, as I cautiously approached, caused the three men, engrossed in fervent recitation of prayers before the image, to turn their heads momentarily toward the tree partly screening me. A fierce fire of pine boughs illuminated the scene, especially the image, which with head once more complete was now in standing position, its face glistening with the libations poured upon it in the course of the prayers. Three women, kneeling back on their heels, were a short distance to the left of the men. During the brief period of observation of the scene, a gourd bowl containing liquid was taken by one of the men to the women who, in turn, appeared to sip from it, before it was taken to the idol and poured upon its face. By their costumes the six participants were probably from the Quezaltenango region, although they may have been Cakchiquel, from the east. I returned to the town in semi-darkness.

Next morning, Dr. Termer and his friend, laden with cameras, and I found the place of worship unoccupied. Embers of the fire smoldered; the

stones were still hot. Some charred remains, possibly of food, in the ancient mortar or stone bowl, and pine tips or needles tied in bundles had evidently been among the offerings. Reconstruction of the altar place between March and December had evidently included skilled mending of the broken image and construction of a terrace on platform of masonry for the larger altar. In this the image had been firmly set in upright position (Fig. 62.1,b). The smaller altar had been separated from the other. Stones which appeared to have been added since my previous visit included the well-shaped *mano*, prominent on the larger altar. The crudely shaped head with a pad like headdress, placed on top of the central cross of the smaller altar (Fig. 62.3,a), is reminiscent of that of an image on horseback. Possibly it is a representation of the patron saint of the town, Santo Tomas, for it resembles a painted wooden image, which, under the name of Tz'ijolaj, has a prominent part in the festival of the saint. The photograph of the larger altar, taken by Termer (1930b, Fig. 17), has previously been published by him.

In the course of subsequent periods spent in Guatemala during 1930 and 1931 I made several more visits to the altar. The ceremonies appeared to be confined to morning and night. Sometimes the prayer makers were alone, sometimes with supplicants. Bundles, probably with maize and other seed ready for planting, were put at the altar while prayers were recited. Among the offerings were little bundles of pine tips and flower petals. In the town churches, too, flower petals often cover the floor altars. The women pluck the petals; the men offer them. Dorothy Reynolds (1946) has a picture of this hilltop altar strewn with petals.

Mr. and Mrs. Treichler, Protestant missionaries in Huehuetenango, who had previously served in Chichicastenango, told me that sometime in 1923 they had happened to be in the shop of Cobar, the druggist of Chichicastenango, when a fellow missionary, Furman, purchased for 25 pesos a number of small objects of jade said to have been the contents of a cache recently uncovered at the place of worship on the hilltop. Sometime later I questioned Manuel Cobar in Guatemala, and he verified the story, telling me that there were 23 pieces, mainly amulets. He had retained three; a large jadeite bead with a crudely incised head, and two amulets, one of which was broken. These I purchased. The large bead, now in Peabody Museum, Harvard University, is crudely incised possibly in representation of the orbital rings and oral ornament of Tlaloc.

The large stone figure with the crossed arms is of a type fairly common in the Guatemalan highlands, and is without doubt of pre-Colombian origin.

62.1. Hilltop altar at Chichicastenango: (a) photograph taken March, 1928, showing statue recumbent and lacking top of head; (b) photograph taken December 1930, showing statue mended and in upright position. (Courtesy of Franz Termer.)

62.2. Ceremonies at the hilltop altar, Chichicastenango: (a) prayer maker at larger altar; small altar beyond; (b) prayer maker reciting prayers with suppliant seated; both photographs taken March 1, 1928.

62.3. Hilltop shrines: (a) smaller altar, Chichicastenango; note head on top of cross (courtesy of Franz Termer); (b) petroglyphs at shrine, Cerro Quemado, Quezaltenango; (c) unidentified shrine near Quezaltenango (courtesy of Gustav Reuthe).

62.4. Shrines near Quezaltenango: (a) cross near cleft with stone heads; (b) cleft with stone heads, apparently of horses; pottery head broken from vessel on ledge above; copal on calabash disks not visible in photograph.

Several statues of that type were in the Kanter collection (Burkitt 1924:138); some have trophy heads, but pendant from the neck, not the waist.

A townsman of Chichicastenango and Mr. Treichler gave the name of this statue as Pascual Abaj or Pascuala Abaj. In that connection one might call attention to a Quiche prayer published in Milla y Vidaurre (1937:1:41), and of which Brigham (1887) gives a translation. This is addressed to "Thou Lord and King Pascual." *Abaj* means 'stone' in Quiche and Cakchiquel (Brinton 1885).

Flavio Rodas and Ovidio Rodas (1938:6, 18–19, 128) illustrate the hilltop altar, and describe a ceremony. The photograph on p. 6 is of interest because it emphasizes the widespread fame of this shrine. The Quiche prayer maker swings his censer as he intercedes for a man identified as a Cakchiquel, although by his dress he appears to be a Tzutuhil

from the vicinity of Lake Atitlan. The authors identify the figure as Turcay, "which the ladinos ordinarily call Pascuala Abaj."

Chichicastenango, alas, is now on an established tourist route. In the luxurious hotel the servants are Indian youths, dressed in the characteristic Chichicastenango attire, including the tasseled headcloth, traditionally distinguishing costume of specific officials, both religious and civil. Worse still, at the Tzanjuyu hotel on the shore of Lake Atitlan, in the Tzutuhil region distant from the Quiche town of Chichicastenango, young Quiche servants also wear the costume of Chichicastenango. This sacrifice of beauty and dignity to the tourist trade has affected even the little place of worship on the hilltop. Termer, in a letter written at the end of 1938, remarks: "Our old friend Pascual Abaj is now the object of tourist excursions. They have rooted out all

the fine trees of pine and *pinabete* which surrounded the place of worship, and this is now in the open air. A broad path has been constructed from the pueblo to the site. Yet Indians celebrate always their customs there."

The more important of two sites near Quezaltenango where ceremonies are held is on the wooded slope of Cerro Quemado, which rises steeply on one side of the road between Quezaltenango and Almolonga. The protruding rock stands like a profile against the dense green of the long hill. Actually, there are two rocks, more than 7 m high, each with a group of incised figures: a lower figure on the larger rock near the cleft between the two, more or less uniting the two groups. Dr. Termer and I visited this site on the afternoon of January 12, 1929. Evidence of a recent ceremony included the head and some viscous organs of a recently killed fowl on a ledge, just below one group of incised figures, and white feathers stuck in groups in the ground below the offerings in front of the stones. Below the lowest figure, that of a woman in squatting position with legs apart (Fig. 62.3b), a fire had been made. The small dishes of hard calabash rind, each about 5 cm in diameter, on which the cakes of copal had been burned, were still around the fireplace. Candles had been placed on juts below the incised figures. Plucked feathers, concealed in bushes in the vicinity, suggested that sacrificial birds might be cooked and eaten at the ceremonial place. On a subsequent visit, in April 1930, I found evidence that candles had recently been burned below the figure of the woman, and there were calabash dishes for incense around the fireplace. A photograph by Gustav Reuthe in my possession shows the head of a sacrificed fowl on the summit of the rock. Termer, in the work cited, gives a vivid account of a scene at this site.

The second site in the neighborhood of Quezaltenango visited by me in 1929 is reached by a foot-

path which led through a maize field to an outcrop of rock. A stone cross was at the foot of the rocks (Fig. 62.4a). In a nearby cleft in the rock were two crude heads in stone, seemingly of horses, and, on a ledge immediately above, a pottery head broken from a pottery vessel (Fig. 62.4b). Nearby were the feet of a pottery vessel, shaped as animal heads, hollow and containing rattle pellets. There were also some offerings of copal on calabash disks.

The owner of the field, an Indian of some education, approached on seeing visitors. He stated that the two stone heads had been found when the excavations were made for the foundations of the cotton mill at Almolonga. The pottery pieces had been found in the neighborhood. He added that he had other recovered "idolos," which he would place there. This information suggested that he was constructing a *brujeria*, possibly exploiting local beliefs and practices. Whether he had placed the cross was not determined. He said, however, that many Indians came to the place.

I include a photograph by Gustav Reuthe of another altar site in the neighborhood of Quezaltenango. Three wooden crosses, a dish to hold offerings; and numerous boughs can be recognized.

WOODSTOCK, ULSTER COUNTY, N. Y.

[The correspondences in the Quiche calendar are: March 1, 1928—7 Kat; March 3, 1928—9 Kame; December 19, 1928—1 Noh; January 12, 1929—12 Imox. Of these 1 Noh alone is important. It is a dominical day. The year-bearer system has largely fallen into desuetude in Chichicastenango, but if the year is the same as that of Ixil, 7 Noh would have been the year bearer for 1928–29. On the other hand, the ceremony on 1 Noh was in all probability connected primarily with the feast of Santo Tomas. The information is not sufficient to say how much the luck of the day affects attendance at these shrines.—Editor.]

Tattooing and Scarification among the Maya

J. Eric S. Thompson

There is a considerable body of material, both in the literature and in archaeological collections, on the practices of tattooing and scarification among the Maya. In view of the world-wide interest in the subject, it has seemed advisable to bring together in print such items as have come to my attention. I would emphasize that these notes, jotted down at random over the past two decades, almost certainly do not exhaust the subject.

Conforming to well-established tradition, we shall refer first to that *vade mecum* of all students in the Maya field, the venerated writings of Bishop Landa. The prelate has this to say on the subject: "They tattooed their bodies [*labravanse los cuerpos*, literally, they decorated their bodies], and the more they do this, the more brave and valiant are they considered, as tattooing is accompanied with great suffering, and is done in this way. The professional workers first painted the part which they wished with color, and afterwards they delicately cut in the paintings, and so with the blood and coloring matter the marks remained in the body. This work is done a little at a time on account of the extreme pain, and afterwards, also, they were quite sick with it, since the designs festered and matter formed. On account of all this they mocked those who were not tattooed" (Landa 1941:91 with slight changes). Elsewhere Landa (1941:125-26) adds that the young men tattooed themselves only to a slight degree before marriage, and that the women tattooed their bodies from the waist up, except for the breasts, and that the designs were more delicate and beautiful than those of the men.

Although tattooing was clearly a mark of valor among the young men, and perhaps was a privilege of persons of noble blood, we find that it was also a punishment, for Landa (1941:121) tells us that if a person of rank was found guilty of theft, his face was tattooed (*labrar*) on both sides from chin to forehead, and this punishment was regarded as a very great disgrace. One must conclude that a special pattern was employed to designate thieves of high birth.

In one passage Landa speaks of scarification (*sajarse*), but the context suggests that he refers to the wounds inflicted to draw blood for sacrifice. The use of the reflexive indicates that the wounds were self-inflicted, whereas scarification for adornment, like tattooing, would doubtlessly have been the work of professionals.

Sanchez de Aguilar (1892:96) gives some interesting details: "For display of grandeur or for attractive appearance they used to cut themselves [*se sajan*] with certain stone lancets which they use on the breasts, arms, and thighs till they drew blood. In the wounds they placed a certain black earth or ground-up carbon. When they were healed, the cicatrices remained with the figures of serpents and eagles which they had made with the lancets. This was a common practice among the Cupuls of Valladolid, my home, where as a child I managed to see some of these tattooed [*labrados*] chiefs. The first friars forbade this old custom, and nowadays [1613] it is not followed."

The author of the *Relacion de Motul*, who was assisted by various Maya, states that tattooing (*labrarse*)

of men took place at the age of twenty-five or over. The men were decorated on the arms, legs, and face; the women, on the breasts and arms.

One of the reasons said to have influenced the renegade Gonzalo Guerrero not to abandon the Maya and rejoin his fellow countrymen was that he had had his face painted and his hands tattooed (*labradas*) according to the Maya custom (Cervantes de Salazar 1914, Bk. 2, Ch. 27). The writer adds that the tattooing of the hands was a privilege conceded only to those who had shown valor.

The book of Chilam Balam of Chumayel (Roys 1933:68) says of a certain Uooh Puc, "There was a glyph *uoh* written on the palm of his hand. Then a glyph was written below his throat, was also written on the sole of his foot and written within the ball of the thumb of Ah Uooh-puc." Similarly, Landa (1941:40) notes of Ah Xupan Xiu that "he wrote on the fleshy part of his left arm certain letters which were of great importance and such as to be respected, they say." The Maya word used for 'written' is *dz'ibtabi*. *Dz'ib* implies the use of a brush to paint glyphs; yet, I think, tattooing is implied, for a glyph painted on the sole of the foot or even within the ball of the thumb would hardly endure half a day.

Thus, for Yucatan we have information on tattooing of the breast, thighs, arms, and hands, and perhaps below the throat, the sole of the foot, and the ball of the thumb. Information on designs is confined to serpents, eagles, and perhaps hieroglyphs.

More to the south, among the Mopan Maya and the Itza, both of which groups were, culturally and linguistically, very close to the Yucatec, body decoration appears to have been more developed.

Francisco Ximenez (1929–1931, Bk. 5, Ch. 58) quotes Friar Agustin Cano concerning one of the Mopan Maya caciques: "He had all his chin, breast, and stomach worked with iron [*labrado á hierro*] with good paintings." Here, *labrado á hierro* must surely refer to the tattooing process, although, naturally, there is no reason to suppose any implement of iron was used. Villagutierrez y Sotomayor (1933, Bk. 8, Ch. 12) writes that the Itza had fine bodies and faces, although some made lines on them [*se los rayaban*] as a sign of valor. Here the Spanish term might refer to either paint or tattoo. However, in another passage, again taken from the diary of Friar Agustin Cano, Ximenez (1929–1931, Bk. 5, Ch. 65) says of an Itza prisoner from Tayasal: "All his breast, stomach and thighs were completely tattooed [*labrados*]. His penis was a monstrosity with very large ears or horns made by hand." Whether this last refers to tattoo or scarification is uncertain. It might result from blood-letting (cf. Gann 1918, Pls. 8, 9; Figs. 15–17). Ximenez (1929–1931, Bk. 5, Ch. 58), again quoting

Cano, says of one Mopan taken prisoner: "His penis resembled a bat with its two wings, and they make it that way and sacrifice to the demon." It is evident, therefore, that this practice was not uncommon in the area. Whether this was a form of scarification or tattoo or a form of mutilation, it is evident from the description of the Itza prisoner, and that of the Chol, given below, that in the Peten the tattooed area of the body was more extensive than in sixteenth-century Yucatan.

Friar Andres Avendaño y Loyola (1696:42v; I quote from a ms. translation of this by C. P. Bowditch and G. Rivera in Peabody Museum, Harvard University) makes a most interesting contribution to the subject in a passage not included in the copious extracts from the manuscript published by Philip A. Means (1917). The friar writes, "Most of them [the Itza of Tayasal] have their faces cut and rubbed with black, and some streaked like black negroes . . . Painting themselves or cutting on their faces the form of the animal which they have as a charm . . ." One can only conclude that the animal depicted was something in the nature of the man's totem or, perhaps, his nagual (familiar spirit). The cuts rubbed with black must surely refer to tattoo rather than scarification since Avendano is speaking of the appearance, not the process.

Ximenez (1929–1931, Bk. 5, Ch. 45), again quoting Friar Cano, writes of one Chol prisoner: "He was painted all over with lines worked with iron [*que se hacen á hierro*], and near his breast he had a chain painted, in the way they paint that of the *Toison*. Furthermore, in the middle of the stomach, in place of the lamb, he had painted a most ugly devil." *Toison* is an order of knighthood, the symbol of which is a wreath of alternating flint and steel. Again the use of the expression *que se hacen á hierro* implies that the work was true tattoo, or perhaps scarification, but definitely not painting.

Ximenez (1929–1931, Bk. 1, Ch. 36) also states that tattooing was common in the highlands of Guatemala: "The most that they had for adornment was to decorate all the body and paint it with a thousand figures. These they made with the very sharp point of a lancet or flint, and, putting on carbon, just as the Moors do, all painted themselves."

Bishop Landa, in the passage first cited, speaks of professional tattooers (*oficiales*). Ximenez (1929–1931, Bk. 5, Ch. 66), again quoting Cano, states that among the Itza of Tayasal the man who painted them was called *Chiquinuitz*, and he was paid in mantles. As we have seen the word *pintar* used where tattooing was meant, it is not improbable that this passage, also, refers to tattoo. *Chikinuitz* would mean 'west hill.'

The tattooers obviously formed a kind of guild. They had their particular deity, Acat (Lopez de Cogolludo 1867–1868, Bk. 4, Ch. 8). *Acat* is translated as inkstand in the Pio Perez dictionary; as a doctor's instrument case or a scribe's pen case in the Motul dictionary. It is evident, therefore, that this deity was closely associated with the tools of the trade. Lopez de Cogolludo makes a statement which unfortunately is somewhat vague, but which implies that the tattooing of a body was regarded as converting it into flowers: "Idolos tambien de los que labran los cuerpos á los indios, que decían se convertían en flores, llamados Acat."

Archaeological specimens show abundant evidence of tattooing or scarification. Designs run from the simplest to the most elaborate. The simplest design is quite prevalent. It consists of a line of dots along the side of the chin: A good example is to be seen on prisoners depicted on Stela 11, Yaxchilan. A somewhat more elaborate decoration is depicted on Stela 12, Piedras Negras. The chin, the corners of the mouth, and apparently the area around the ear are treated. A use of spirals and curves around the mouth and on the side of the chin occurs on Lintels 24 and 26, Yaxchilan. A still more complicated design is to be seen on a pottery figurine from the Usumacinta Valley now in the American Museum of Natural History which was exhibited in "Twenty Centuries of Mexican Art." This has tattooing or scarification on both cheeks, around one eye, and on the chin. In fact, many pottery figurines from the lower Usumacinta River northward across the coastal parts of Tabasco and Chiapas show tattooing in various amounts. Blom and La Farge (1926–1927:1:99) note that it is almost always present on figurines from Jonuta. Figurines from the island of Jaina occasionally show rather elaborate tattoo or scarification (Ruz 1942, 1945a, Fig. 340), but only in Yucatan is the art fully developed. One of the finest examples is on a head in the mouth of a serpent, a facade ornament, from Uxmal (Seler 1917:90). The decoration covers the chin, and continues around the corners of the mouth and across the cheeks. There are some interesting examples of facial decoration at nearby Kabah, on door jambs and at least two stone jars. One of the designs encircles the eye, makes a loop around the cheek, and ends at the chin, forming a cursive G. Schellhas (1904:600–601) discusses and illustrates examples of tattooing or scarification on figurines attributed to Yucatan in the Völkerkunde Museum, Berlin. One is particularly interesting in that the design around the chin represents the fleshless jawbone, a Maya symbol of death.

As an example of well-executed tattooing in the Guatemalan highlands, one might call attention

to the right-hand figure on the Fenton vase from Nebaj (Joyce 1914, Pl. 24). This consists of an oval around the mouth with short spirals at each end. A pottery figure which shows definite scarification, as opposed to tattoo, is illustrated by Villacorta (1938:95). This is the figure of a woman holding a pot, and is attributed to Finca el Mixqueño, near Patulul, in the department of Suchitepequez. In all probability it belongs to the class with rectangular bases. Each arm is decorated with about half a dozen "coffee beans" in low relief, and there are several shallow disks on the breasts. It is probable, however, that this finely modeled figurine is the product of Pipil, not Maya, hands. Another portrait of a woman with what may be scarification marks on the arms is illustrated by Dieseldorff (1926, Fig. 53). The figure is of the same general type as that just cited, and is said to have been found at Santa Ana Mixtan, in the department of Escuintla. This was almost certainly Pipil territory in the fifteenth century. The marks are similarly arranged in vertical rows, but consist of disks with an inner circle, perhaps made with a tubular drill.

Disks appear on the bodies of a few Itza personages depicted in the temples of Chacmool and the Warriors at Chichen Itza (Morris, Charlot, and Morris 1931: 243, 244). In one case the disk is painted red and outlined with black, leading Charlot to suppose this represents genuine tattooing. In view of the disks on the figure from Finca el Mixqueño, which, as noted, may well be of Pipil manufacture, it is interesting to find this same design on the bodies of the Mexican or Mexicanized Itza. The Pipil and Itza share quite a few distinguishing traits, and it is not improbable, therefore, that this design is Mexican, and was carried by both groups of immigrants to their new homes.

Mention should also be made of one other characteristic decoration, although this possibly is neither tattooing nor scarification, but disks stuck on the skin. This occurs on many figurines, particularly those found near Lubaantun, in southern British Honduras (Joyce 1933, Pl. 1), along the upper Usumacinta and the area immediately to the south extending toward Alta Verapaz, and also in the coastal area around the mouth of the Usumacinta. The decoration consists of one or more plain disks set in a vertical line down the center of the forehead, like the caste marks of India. Most usually there are three of these disks in a row. They are frequently worn by women, and, in fact, may only have been worn by women. They can hardly be ornamental, but might, perhaps, denote rank, group, or status.

One has the impression that the more complex forms of tattoo and scarification occur in the western

and northern parts of the Maya area, and, in view of the prevalence of the custom among non-Maya peoples in southeastern Veracruz, it is not impossible that this custom was borrowed by the Maya from their western neighbors. The finest tattooing appears to date from the eighth to the tenth century. Scarification, on the other hand, certainly has a much earlier development, since it is to be seen on figurines of the Mamom phase at Uaxactun (Ricketson and Ricketson 1937, Pl. 70e, f).

The archaeological catalogue of examples of tattooing or scarification could be greatly extended. My intent, however, is merely to show that the archaeo-

logical evidence supports the accounts of the early writers, and also to indicate that the custom has a respectable antiquity. Unfortunately, so far as I am aware, archaeology has produced no examples of the pictorial decoration described by Sanchez de Aguilar and Avendaño. All designs appear to be geometric. In the various accounts of the practice there is no mention of any color in addition to black, although, as we have seen, red and black tattoo marks may occur in the Temple of the Chacmool, Chichen Itza. It is very much to be doubted that Maya tattooing ever approached the high levels reached in eastern Asia and Polynesia.

The Tamiahua Codices

R. H. Barlow

Three lithographed maps, tinted in bright water-color, were given me for publication in 1944 by Sr. Guillermo Echaniz, who retained duplicates. Another collection was shown me later by Sr. Pompa y Pompa, in the library of the Alzate Society. Obviously intended for publication in the nineteenth century, they bear no identification other than the phrases "Tip. y lit. Correo Mayor 410, Mex.," "Lam. 2" and "Lamina 3a," the remaining map obviously representing Lamina 1. Each drawing measures 28.5 by 36 cm, exclusive of the legends.

Though abounding in hieroglyphics, only the third bears inscriptions in the Roman alphabet. This identifies such town as Tamiahua (Chamiagua Vieja?), Tamapach (anciently Tamapatsco, now Temapache) and Tepecintlan (Tepetzintla), all of which lie to the north of Tuxpan, Veracruz. Other place names (Guauchinango, Pantepetl) may be located east of Tuxpan, so it is clear that Lamina 3, at least, refers to the Huasteca Veracruzana. I have called the group the "Tamiahua Codices" for lack of any precedent.

Sr. Pompa y Pompa accurately observed that all three maps seem to refer to the same place, perhaps in different periods. This is supported by the presence of the same shoreline featuring a promontory between two rivers, the northernmost or right-hand one shaped like a Y, in all three maps. One likewise observes that in Maps 2 and 3 the southern bank of the left-hand river bears the hieroglyph of Tlazolteotl; and that the roads leading inland begin at a place bearing an animal name and end at another somewhat resembling the first. Maps 1 and

64.1. Tamiahua codex.

2 abound in drawings of native gods, Tlazolteotl, Ehecatl, Tlaloc (near the fork of the Y, Map 2), and cult objects (pantli and tzompantli), whereas Map 3 features Christian churches.

These pagan gods, known to be associated with the Huasteca, together with the nose plugs, shields, and expertly stylized hieroglyphs, incline me to accept the maps as authentic copies of some (to me) unknown originals, which a nineteenth-century student intended to publish, or perhaps actually did publish. If they are fakes, they are brilliant fakes. What is decipherable in them makes sense. Map 1 seems to hint at a local peregrination, at a date when

64.2. Tamiahua codex.

64.3. Tamiahua codex.

there were few settlements in the area. Perhaps the dot numbers 3, 4, 7, and 13 Tecpatl explain the tribal sojourn at various points. The itinerary seems to lead south from the land between the rivers, during wartime (cf. shield and arrow symbols). Map 2 is the most complex and handsome, presenting half a hundred place names for future decipherment, and showing no trace of European influence as yet. Map

3 is the usual story of a collapsing graphic tradition depicting colonial events.

From the northern Veracruz area we have little similar material. The codex of Huachinango, found in a box in a ruined city during the French intervention and published by Zelia Nuttall in *Man* a quarter of a century ago, is the only specimen that occurs to me.

The Malinche of Acacingo, Estado de Mexico

R. H. Barlow

Below Tenancingo (Estado de Mexico) lie the small settlement of Acacingo and, to the west of this, the Cerro de la Malinche. On the latter exist various carvings, or remains of carvings, for in one place an outcropping of petroglyphs has recently been blasted with dynamite by someone eager to detach salable portions. Elsewhere appear fortifications, sentry posts (reminiscent of Nezahualcoyotl's Bath), and a shrine. These are on the west side of the hill, commanding an ample view of Tecualoyan, Zumpahuacan, Iztapan de la Sal, and other towns in the southern part of the state.

During a brief visit to the Cerro I was able to make a drawing of the shrine, which somehow missed the vigilance of the early church and has not yet been mutilated by the traffickers in antiquities. The simplicity of the monument, a single stone, perhaps 1.5 m tall and 1.9 wide, is balanced by the magnificence of the setting, a cliff-wall facing towns and rivers and cloud-filled space to the west and south.

This carving, "la Malinche," guards a trickle of water, and from her two bunches of plumes one recognizes Xochiquetzal, the first woman to bear twins and a popular goddess in nearby Morelos. At the nape she wears the water-goddess fans, *tlaquechpanyotl*; her face is framed in a serpent helmet with stylized eyes.

Whether the object in her clasped hands be the pendant of her necklace, another object appropriate to fertility goddesses, a heart, or something else, I do not know, but I guarantee the accuracy of my drawing. At the meeting point of her index fingers appears a shallow hole where some precious stone perhaps was embedded.

65.1. The Malinche of Acacingo.

The date, 2 Acatl 1 Tochtli, I relinquish to the reader of these notes. The year 2 Acatl is, of course, that of the New Fire ceremony, and the whole style of the monument looks to me immediately pre-Hispanic.

Three Zapotec Stones

Heinrich Berlin

When I was at San Miguel Sola, Oaxaca, at the beginning of this year, my attention was called to three archaeological stories in the neighboring village of San Juan Sola. Father Jose Aurelio Garcia, the Catholic priest of San Miguel, gave me the information about their discovery.

Some time ago when visiting San Juan he happened to stroll around the small jail, at the back of which he found the three stones built into the wall. He had them removed to the small plaza of the village. It is supposed that they came from the neighboring hills, which apparently hold further archaeological remains.

Stones 1 and 2 (Fig. 66.1b, c) are very much alike, the measurements of both differing only slightly.

	Stone 1	Stone 2
Height of visible part	1.40 m	1.50 m
Width of front	0.35 m	0.50 m
Thickness front to back	0.50 m	0.35 m

I have not yet found a satisfactory explanation of the use of these stones, but since they are so similar it is highly probable that they were both used for the same purpose. One is tempted to associate them with a ball court where rings were used, as both stones show the typical double T with attached circle. The same double T and circle are on the opposite side of the stones (not visible in the pictures).

The third stone (Fig. 66.1a) clearly is Zapotec, since it is a stela with Zapotec hieroglyphs written

66.1. Zapotec carved stones: (a) Stone 3, stela with glyphs; (b) Stone 1; (c) Stone 2.

on it (Length 1.35 m width of front 0.33 m, thickness front to back 0.30 m).

I offer some suggestions which may help in the decipherment, under the assumption that the four main hieroglyphs are calendrical and that the additional elements represent numbers connected with them.

The inscription, reading from below upwards, starts apparently with a bar, which is to be read as 5. Then follows a hieroglyph which I am inclined to identify with Caso's (1928) Glyph J. Between the two portions of this glyph are inserted two circles which do not seem to belong to the glyph itself. One can interpret them as 2, add them to the mentioned bar, and then read the whole as 7 J.

Above this hieroglyph is Caso's Glyph D, combined with two circles, thus reading 2 D.

Then follows Caso's Glyph L, also with two circles, but on both sides of the upper scrolls of the hieroglyph are two hooks Caso (1938) interpreted similar hooks on a painting of Tomb 105 at Monte Alban as the outer ends of a 5-bar. Applying the same interpretation here, we would have to read 7 L.

Finally the inscription ends with Glyph D once more. As there are two circles, the whole reads 2 D as before. A little above these two numerical circles are two other smaller dots, differing from the circles in size and having no inner circles. Therefore it is likely that they are not numerical but rather ornamental space fillers.

MEXICO, D.F.

Blowguns in Guatemala

Edwin M. Shook

The blowgun is in use today among the Mam Indians of western Guatemala and their neighbors on the east, north, and west. These are the Quiche, Cakchiquel, Tzutuhil, Ixil, Kekchi, Chuj, Jacalteca, and several Indian groups to the west of the Mam in the highlands of Chiapas, Mexico.

In an effort to protect small game and particularly the quetzal bird, the Guatemalan national symbol of freedom, a law was passed about 15 years ago prohibiting the use of the blowgun. In areas where administration of the law was possible it was so rigorously enforced that the blowgun as a hunting weapon has been abandoned. Its use persists, however, in the more remote settlements.

Two blowguns have been purchased at Finca El Porvenir. The first was bought from the farm administrator in August 1942, the second in February 1916 from a Mam Indian, who had brought it from his home village of San Ildefonso Ixtahuacan in the southern part of the Department of Huehuetenango.

Finca El Porvenir is a huge farm situated approximately in the center of San Marcos, the westernmost department in the Republic of Guatemala. It occupies most of the southern slope of the Volcano of Tajumulco and overlooks a portion of the Soconusco region of the Pacific coastal plain. The Pacific Ocean, 60 km to the southwest, is visible from Porvenir. The farm lands range from 600 to 3,150 m elevation and contain large plantings of coffee and cinchona as well as subsistence crops of corn, beans, chile, bananas, and plantains. The maintenance of cinchona and coffee requires a considerable amount of resident labor,

and during harvest the number of workmen is more than trebled. The additional labor comes from all over the Departments of San Marcos and Huehuetenango, and in exceptional instances has been recruited from even as far as Chiquimula in eastern Guatemala and all intervening departments. The finca offers an unusual opportunity, therefore, for study of the customs of Indians from many sections of the country.

Indians speaking the Mam language of the Maya stock predominate among both the resident and transient labor forces at Porvenir. The blowgun is used by them there and in their villages for hunting birds, rabbits, squirrels, and other small game. They are proficient in its use, and the hunter is jeered by his companions if a hit is not scored on a small bird at a 20 m distance. Accuracy becomes progressively less up to 50 m, which appears to be the maximum effective range.

La Farge and Byers (1931:64) in their study of the Jacalteca of northern Huehuetenango gave the following description and use of the blowgun. "The blow-guns are hollow tubes of some light wood which grows in the Cold Country around San Miguel and Santa Eulalia, where there are people who specialize in making them. The gun is usually about 50 cm longer than the individual who uses it. The longest seen was 192 cm long (a little over six feet). On one side of the gun is placed a lump of beeswax which serves as a sight. Pellets of clay are used for bullets, *spa-up:al*. These are rolled into approximate size in the hands and carried dried in a small pouch. The ones for immediate use are worked down to the

67.1. Mam Indian using blowgun, Finca El Porvenir.

exact size between pieces of bark or by rotating them in the mouth of a brass rifle shell, *kaski'ya* (Spanish). The shots that have been thus prepared are carried in a small pocket on the outside of the pouch, ready to hand. According to statements made to us, a rabbit can be brought down with this weapon at a distance of fifty yards."

The blowguns purchased in Porvenir are identical in workmanship and differ only in details of measurements. The barrels, made of well-dried white pine or cypress, consist of two halves glued and nailed together, the work being done by hand with such infinite care that an almost perfect bore results. One blowgun measures 148 cm long, 1.3 cm diameter of bore, 3.1–3.8 cm outside diameter. The second measures 172 cm long, 1.21–1.28 cm diameter of bore, 3.2–3.7 cm outside diameter. In outside diameter each barrel tapers slightly from the muzzle to the mouth end, which is beveled to fit the mouth (Fig. 67.2a).

A Mam Indian informant from Concepcion Tutiapa, Department of San Marcos, reports two small trees much sought after for making blowguns. These are the "moquio" found in the Porvenir forest, and the "ixkepatze" which grows in the region of Concepcion Tutiapa. Both have straight branchless trunks with soft pithy hearts. They are carefully

selected for diameter and straightness, cut, and the bark removed. Then, some makers of blowguns will allow the pole to dry for five or more days before removing the soft heart; others will bury the pole in mud or under water for five days allowing the pith to rot before removing it. My informant claims that the blowguns from the moquio and ixkepatze are the finest and most accurate. He emphasized his statement by quoting the price of these guns at double the price of those made in two pieces, because the latter are likely to open at the seams, causing a loss of air pressure and thus decreasing their effectiveness.

The gun barrels, when thoroughly dried and the bore cleared, are treated on the exterior with several applications of beef tallow to prevent further drying, or shrinking and cracking of the wood. The tallow and continued usage give the gun barrel the rich color of dark stained mahogany.

Finally a gun sight, consisting of a single brilliant red bean impressed in a lump of beeswax, is placed on the barrel 20 cm from the muzzle end. The beeswax encircles the barrel and forms a large lump directly below the gun sight (Fig. 67.2a, e). This acts as a balance to keep the sight upright. The wax is obtained from the hives of a small wild bee, locally called "congo."

67.2. Details of blowgun: (a) longitudinal section of blowgun: 1, 2, two halves of barrel, glued and nailed together; 3, beeswax; 4, red bean (gunsight); (b) side view of blowgun; (c) bamboo polishing tool; (d) clay pellet, 1.8 cm diameter; (e) cross section of gun, sight, and beeswax balance.

I received about 50 unfired clay pellets with the blowgun from San Ildefonso Ixtahuacan, and a small bamboo tool for wearing down and polishing the pellets. Only a few of the clay pellets were of a size to fit the gun, the remainder being roughed out marbles of clay slightly larger than the gun's bore. The finished pellets averaged 1.18 cm diameter, ranging from 1.10 to 1.20 cm; they averaged 1.74 grams in weight and varied from 1.62 to 1.81 grams. Unfinished pellets were all greater than 1.21 cm in diameter and averaged in weight 2.38 grams. The lightest pellet weighed 1.96 grams and the heaviest, 2.92 grams. The size of the blowgun necessitates the pellets being less than 1.21 cm diameter to be successfully fired through the barrel. Best firing results are obtained with a pellet as close to the bore diameter as possible without jamming. The vendor stated that the pellets were obtained from natural clay found in the vicinity of his village. The clay was finely ground between stones, then enough water added to make the clay malleable, and pellets rolled out by hand as youngsters everywhere make clay marbles. These are allowed to dry thoroughly and, if the diameter is correct, are ready for use in the blowgun. The tubular bamboo tool (Fig. 67.2c) is used to wear down the pellets to size, round, and polish them. A more successful tool, when obtainable, is the metal shell of a .44 caliber cartridge. Thompson (1930:88) has noted the use of a section of bone for the same purpose among the Mopan Maya, and he informs me that a bone shaper is used also by the Kekchi of the Alta Verapaz.

The age of the blowgun in Guatemala is probably considerable. In Porvenir I have found unfired clay pellets among surface sherds of plumbate ware. This cannot be assurance of the preconquest usage of the blowgun, but better evidence of its age was apparently obtained by Bertha P. Dutton and Hulda R. Hobbs (1943:62). They found spheres, cane of plumbate ware, in the ruins of Tajumulco, a site approximately 20 km due north of Porvenir. These they believe to have been blowgun pellets. Also they refer to the present day use of the blowgun by the Mam Indians of that region. Linné (1939) recovered in his archaeological excavations at Teotihuacan and Culpulalpan in Mexico a number of clay pellets of a size suitable for blowguns, and a carved pottery fragment depicting a hunter with a blowgun. These finds probably belong to the Middle Culture of Central Mexico. Thompson (1930:88) has collected a number of references to the blowgun in early literature. He also notes that among the Kekchi and Mopan Maya the blowgun tubes are prepared by submergence in water to rot the pith.

As yet, I have been unable to find a Mam name for the blowgun or pellets. The Mam use the Spanish words "cerbatana" for blowgun, and "bodoque" for the clay pellets. The Chuj of northern Huehuetenango and the Quiche use "pub" for the blowgun. Stoll in 1883 listed names for the blowgun among the Peten Maya, Kekchi, Pocomchi, Pokoman, Cakchiquel, Uspantec, Ixil, and Quiche (Stoll 1883).

FINCA EL PORVENIR
GUATEMALA

A Reconnaissance of El Rincon del Jicaque, Honduras

Gustav Strömsvik and John M. Longyear III

The backbone of organized resistance offered by the Indians of western Honduras to Spanish rule was finally broken in April 1530, when Hernando Chaves besieged and conquered the stronghold of the Maya chieftain, Copan Cael. The story of this siege, told by Francisco Antonio Fuentes y Guzman in 1689 (Morley 1920, App. V), is well known to all students of the literature concerning Copan. In recent years, coincident with the revival of archaeological activity at Copan, much thought has been directed toward locating this conquest site. It would be almost impossible today, however, to find the spot described by Guzman: a site "defended to the south by the extended mountain range of Chiquimula de la Sierra, to the north by that of Gracias a Dios, to the west by a ravine running north and south and filled with the waters of the famous Copan river" (Morley 1920:543). From this it would appear that the stronghold lay in some intermontane basin bordering on the Copan River, but the description is hardly explicit enough for a search, 400 years later, without a great deal of luck, not to mention imagination. Furthermore, Guzman's account of the ruins of Copan, included in the same document, is so fanciful that doubt must also be cast on his accuracy respecting the site of Chaves' successful campaign.

In 1834, Juan Galindo included in his report (Morley 1920, App. XI) on Copan to the Guatemalan government a brief paragraph describing some ruins known to the natives of this district as "Conquest." That Galindo, 300 years after the event, had hit upon the location of the fortress besieged by Chaves must

also be open to doubt, but at least his description was sufficiently confining to encourage a Honduran archaeologist, Sr. Rafael Girard, to search for the site. In 1944, Girard came upon a place near Esquipulas called "El Rincon del Jicaque," which not only conformed with Galindo's (1836) description in almost every respect, but also contained mounds, pottery, and other evidences of previous human occupation. The finding of one, at least, of the "conquest" sites in the literature had thus been established, and the way was open for further investigation. In March 1946, Professor Jesus Nuñez, Director of the Archaeological Museum at Copan, paid a short visit to El Rincon del Jicaque, and a few weeks later Gustav Strömsvik and Prof. Nuñez spent a week at the ruins, making a plane-table survey of the mounds (Map 68.1) and sinking several test pits for pottery. The present report is based on the findings of this last expedition.

DESCRIPTION OF THE SITE

Thanks to the airplane, the site of El Rincon del Jicaque is today readily accessible. The town of Ocotepeque, Honduras, is a 15 minute flight from either the ruins of Copan or the city of San Salvador; and from here mules can be taken to the ruins, which are a four hour ride distant, the road following the left bank of the Lempa River, in the direction of Esquipulas. At the settlement of Piñuelas, about an hour's ride from the ruins, guides and workmen can be obtained, and it is here that anyone wishing

68.1. Rincon del Jicaque, Honduras.

to spend more than one day at the site must stay, for camping at the ruins is precluded by the difficulty of obtaining water there.

The town of Piñuelas, itself, is of interest to the imaginative historian. The date of its settlement is far in the past, well beyond the memory or knowledge of even the oldest inhabitants. The people of

this little valley are light colored, with little Indian admixture apparent, and most of the families bear the name of Polanco. Can it be only coincidence that one of Hernando Chaves most trusted captains was named Gaspar de Polanco, or are these settlers the present day descendants resulting from some of that doughty warrior's less military conquests?

El Rincon del Jicaque, the name given the ruins by the people of Piñuelas and surrounding villages, has no connection with the conquest or with the ancient Indian population. We were told that, many years ago, a Jicaque Indian was brought up in one of the nearby settlements. He repaid his adopters by running away with one of the village maidens, the couple choosing the peninsula bearing the ruins as a hide-out. A considerable posse had to be employed in order to capture the Indian and bring him to justice and, ever since that occasion, the ruins have been known as El Rincon del Jicaque, or "refuge of the Jicaque."

Galindo's description of this site runs as follows: "Four or five leagues from Esquipulas is the place popularly called 'Conquest'. It is a peninsula formed by the Lempa River, and in part by a brook which unites with that river to the south, the waters running through a very deep canyon in the vicinity, leaving to the south a single narrow entrance. After traveling some distance through it, a stone trench is encountered, with many quarried stones, which crosses the isthmus where it is not wider than 20 yards. After passing the trench, a plain of about 200 yards in diameter is found, surrounded by the river and elevated above it by perpendicular precipices more than 100 yards. The side opposite the peninsula is level with it, but at the distance of a rifle shot. As a point of defense it was excellent, the besieged having supplies of provisions and the means of drawing up water from the surrounding abyss."¹

Our present expedition found this description accurate in most respects. As we approached the ruins from the south we circled a large hill near the peninsula and then noted a depressed area in the ground, 2–3 m wide and about 0.25 m deep, running straight to the narrow entrance of the site. This depression may be the remains of some kind of road, but no pavement or flooring of any kind could be found. A stout wall of stone, completely shutting off the narrow neck of the peninsula, was next encountered (Fig. 68.11.). The wall at present is about 2 m high, of medium-sized uncut tuff boulders, and built in four sections, this seemingly the result of patchwork and not of rational planning. A break in the wall, probably of fairly recent date, affords passage to the site. Although Galindo wrote of a trench crossing the entrance, no trace of one was found, nor were any cut stones seen, either here or elsewhere in the ruins. Since, however, Galindo made no mention of the wall, certainly the most prominent feature of this neck of land, it is possible that he interpreted the word "trinchera" to mean a fortification in general, rather than an intrenchment. There have been more confusing errors made by persons writing in a foreign language.

Once inside the wall, one sees an arid plain, its flat surface broken only by a few pines and scrub oaks. A thin layer of humus lies directly on the soft tuff which forms the bedrock of the peninsula. The Lempa River, some 80 m below the plain, is the sole source of water, and it can be reached from within the wall only by climbing down a set of toe holds cut into the rock on the east side of the mesa. These toe holds descend an almost perpendicular cliff, 4 m in height. None of the expedition attempted the climb, but a couple of boys from a nearby settlement demonstrated that it could be done. On the mesa top, no construction or natural formation was noticed that could possibly have served as water storage tanks.

Although foundation walls of house sites appear all over the plain, only one is of vaguely pyramidal form, justifying the title "mounds" (Fig. 68.1k). This last may well have been the location of a shrine or altar. The great majority of walls consist of only one course of stone; one foundation has three crude stone steps on its south side. As noted above, no squared or cut stones were seen. Most of the house sites are oriented with their long axes about 20 degrees east of north (magnetic). A trench was dug through one of these foundations to determine the construction of the shelter once erected upon it. The very small amount of debris would seem to indicate it had wattle-and-daub walls and a thatch roof, with a floor of hard tamped clay or disintegrated tuff. Artifacts were very scarce. A few broken manos, with two grinding surfaces, were recovered, together with a couple of small greenstone celts and several obsidian flakes and cores. No other specimens, aside from pottery, were found.

ARTIFACTS

Although the equivalent of ten man-work-days were spent in trenching at various spots in the ruins, only a small, amount of pottery was recovered, all of it from deposits located west of the western row of house mounds. The sherds can be classified into two wares, brown and red, the former having a numerical advantage over the latter of about 4 to 1. All specimens were more or less badly weathered, since they lay close to the surface in the thin stratum of soil covering the bedrock.

Brown ware sherds have a stick-smoothed surface, light sandy brown in color. The paste matches this surface color, with a darker core (dark brown to black) being almost invariably present. Paste and temper both are coarse in texture. Red ware is similar to the above in both surface and paste, the distinguishing feature being a thick, soft slip of hematite

68.2. Rincon del Jicaque, Honduras.

red. All red ware sherds found were slipped on both surfaces.

Vessel forms are few and simple. One of the two most common is, as one might expect, the storage jar. This has a globular body with dimpled base, the neck being somewhat constricted and then outcurving to the lip (Fig. 68.1a). Diameters at the lip run 24–28 cm at the point of greatest neck constriction, 18–22 cm. This form occurs in both brown and red ware, the only difference in the two being in the use of handles and, possibly, decoration. Judging by the number of handles recovered, brown ware storage jars must have borne at least two, and perhaps three, horizontally placed on the body of the vessel. The handles are simple loops, with a span ranging between 5 and 6.5 cm. Red ware handles, on the other hand, are very scarce, and none of the specimens give any indication of their location on the jar. Decoration is simply disposed of. No brown ware sherds bear any trace of design, painted or incised. A

single red ware rim sherd, however, has a fragmentary linear pattern painted in black on the exterior, just below the rim (Fig. 68.1d), so we may assume that some, at least, of the red ware jars bore painted decoration.

The other common vessel shape is the comal, a large shallow plate used today, as presumably in the past, for cooking tortillas. The Rincon del Jicaque specimens measure 25–35 cm in diameter, and bear horizontal loop handles on the rim (Fig. 68.1b). Judging by more complete comales found at other sites, these handles are two in number, opposing each other. The handles on the largest comales found at El Rincon del Jicaque are flattened in section and have a span of about 7 cm. On smaller plates, the handles measure 3.5 cm in span (Fig. 68.1e). A number of comal rim sherds have merely perforated “ears,” possibly for string suspension (Fig. 68.1f). All of the comal sherds are of brown ware, and none of them are decorated in any way.

The only other recognizable vessel form represented by the sherds is an undecorated hemispherical red ware bowl, with a mouth diameter of 15–25 cm (Fig. 68.1c). This shape is somewhat less common than those described above.

There is one example of incised decoration among the Rincon del Jicaque sherds. A single coarse brown ware fragment, with very thick walls and unsmoothed surfaces, bears a crude incised hachure design on one surface (Fig. 68.1g). Vessel form cannot be distinguished.

Fragments of three crude, handmade figurines were found. Two are legs, one bearing a foot with toes indicated by gashes of irregular length and spacing. The third fragment is of a head and torso (Fig. 68.1i). Eyes and mouth are indicated by deep gouges, the former single and the latter double. The nose is pinched up, with a dishd-out area above, representing the forehead. At the sides of the head, ears are faintly represented by pinching, with a hole at the base indicating the earplug. On the torso, two holes pierce the body from front to back in the places usually occupied by the breasts.

The stone industry of El Rincon del Jicaque is as poor as the ceramic. Long obsidian flakes, undoubtedly used for knives, are fairly common. Most of them have been secondarily flaked along the edges, probably through use. One irregularly shaped flake may have been employed both as a drill and as a dartshaft scraper (Fig. 68.1h). Polished greenstone celts are represented by one complete and two fragmentary specimens, the former measuring 14.3 cm long and 2.9 cm wide at the cutting edge. These celts were probably hafted in wooden handles similar to the one found by Gordon (1898) in a cave at Copan. Since no cut stone was found at El Rincon del Jicaque, these celts could not have been used for that purpose, but were probably employed in cutting wood and, possibly, as war hatchets.

Not a single artifact of Spanish or colonial origin was recovered, either on the surface or in any of the test trenches.

SUMMARY AND CONCLUSIONS

El Rincon del Jicaque is a fortress situated on an isolated peninsula formed by a bend of the Lempa River and cut off from the "mainland" by a strong artificial wall. The ruins consist of a number of low foundations, built of uncut tuff boulders, and one higher mound, which may have supported a shrine. Toe holds cut into the cliff afford precarious access to the Lempa River below, but no water storage facilities, natural or artificial, exist on the surface of the plateau.

The ceramic industry is poor, both in quantity and variety. The only vessels represented by the sherds are storage jars, in brown arid red ware, brown ware comales, and red ware bowls. Decoration is virtually nonexistent. A few crude handmade figurines complete the pottery tally. Stone work is represented by a few obsidian knives and greenstone celts.

The above evidence makes it quite clear that El Rincon del Jicaque was not a permanent occupation site but rather a place of refuge, to which the inhabitants of the surrounding region retired in times of stress. There is no stratigraphy in the thin layer of soil overlying the bedrock, but the occurrence of storage jars in two different wares may be evidence that the site was used over a considerable period of time. On the other hand, this might also be an indication that two different peoples visited the place on various occasions.

The age of the ruins is difficult to determine, since the pottery cannot be compared with that of any of the better-known sites in the area, such as Copan, nor do the figurines resemble any previously reported upon, except in a very general way. The complex as a whole, however, is late rather than early in appearance. The obsidian flakes and greenstone celts are indistinguishable from those found all over the region, but, since these appear to have been extremely stable and long-enduring cultural traits, they cannot be used in dating. We think it safe to say, however, that El Rincon del Jicaque is late, probably falling in the period of unrest immediately preceding and contemporaneous with the Spanish conquest. The very nature of the site suggests this and, while the presence of Spanish artifacts would confirm this dating, their absence, in view of our very limited excavation, is not conclusive.

There can be little doubt that this is the place described by Galindo in 1834. Whether it is the site of Hernando Chaves' victory over Copan Cael is, however, another matter. Galindo did not so commit himself in his account; and we here follow his cautious example. If Fuentes y Guzman, departing from the extravagances of his description of Copan, gave us a true report on the conquest site, we must look elsewhere for the location of his tale of deep intrigue and high courage.

NOTES

1. "Cuatro o cinco leguas de Esquipulas se halla el parage llamado vulgarmente 'la Conquista' (vea el No. 26) es peninsula formada por el rio de Lempa i en parte por un arroyo que se le une del Sur, corriendo las aguas en una barranca hondisima [sic] a su derredor, dejando del lado del Mediodia, una sola i estrecha entrada; cami-

nando por esta algun espacio se encuentra una trinchera de piedras, muchas de ellas canteadas, que atraviesa el istmo [istmo] donde no tiene este mas de veinte varas de ancho; pasada la trinchera se halla un plan, como de doscientas varas de diametro, rodeado del rio i elevado de el mas de cien varas por precipicios perpendiculares. El lado

opuesto a la península esta a su nivel pero a distancia de taro de fusil largo. Como punto de defensa era este excelente, teniendo los sitiados acopias de viveres i modo de subir el agua desde el abismo circunvecino." (Copied from the Peabody Museum of Harvard's photostat copy of the original manuscript.)

"Rim-Head" Vessels from Kaminaljuyu, Guatemala

A. V. Kidder and E. M. Shook

From time to time there have turned up at the great archaeological site of Kaminaljuyu, in the northwestern outskirts of Guatemala City, fragments of an interesting type of presumably ceremonial vessel, whose rim bore large human heads. Some of these were brought in for sale by people living in the vicinity, others were found by us among sherds of the Miraflores phase thrown out from road cuts and adobe makers' pits. We therefore believed the vessels to have formed part of the Miraflores complex, the earliest so far surely identified at Kaminaljuyu and thought, because of the nature of its hand modeled clay figurines, to belong to the group of "archaic" Mesoamerican cultures. We could not, however, be certain of this assignment until a small but unmistakable piece of one of the characteristic heads came to light in checking other material from a pure Miraflores deposit in a stratigraphic test made by R. E. Smith in 1938 on Finca Miraflores, a part of the Kaminaljuyu site.

The vessels are of course, unslipped, reddish brown ware; the surfaces, particularly the heads, are well smoothed but unpolished; the paste is a warmer brown thickly sown with particles of white temper, presumably volcanic ash. They were almost surely tripods, probably with a head set above each of the solid, truncated conical feet (Fig. 69.1a). Although no piece is sufficiently large for accurate measurement, the lip diameter of the flat bottomed bowls evidently ranged from about 45 to 55 cm. Thickness of walls and base, 1-1.4 cm; of the heads, slightly less.

69.1. "Rim-head" vessels, Kaminaljuyu: (a) restoration based on fragment shown in *d*; (b) three-quarter view of head shown in Fig. 69.2a, lower left; (c, d) section and front view of head in Fig. 69.2a, second from left, upper row; the vent, shown in section as at back of head, is actually toward left side (cf. Fig. 69.1b); total height of *d*, 29 cm.

69.2. "Rim-heads" and fragments, Kaminaljuyu: (a) all examples of this type found to date; for drawings of second head from left, upper row, see Fig. 69.1c, d; of head at lower left, Fig. 69.1b; (b, c) front and side views of head shown in a, second from left, lower row; total height of b, c, 25 cm.

The hollow heads are remarkably uniform. Looking outward, they rise, at the back, from the floor of the bowl; the chin rests on the straight, somewhat flaring wall. They are high, round topped, and above the level of the eyes almost perfectly circular in section. A single round vent, 1.2–2 cm in diameter, has in each case been punched through the wall toward the left side, usually below the level of the ear. Of the two specimens sufficiently complete to have retained such an object, one (Fig. 69.2b) contains a single clay rattle pellet, the other does not.

There is no representation of hair or headdress. The eyes, two flat and more or less elliptical pellets of clay, are set in shallow horizontal depressions pushed inward while the head was in the leather hard stage. The upper edges of these depressions form rather realistic, but otherwise unmarked, eyebrows. The cheeks were slightly swelled outward by pressure from within. The prominent nose was modeled on, but, unlike the eyes and the round buttons on the sides of the nose, the lines of its junction with the surface have been obliterated; whether these depict ornaments or the sides of the nostrils is uncertain. Most characteristic is the out-thrust, pouting lower lip that rises from the small chin. The ears are short flanges set at right angles to the head; at their lower ends are round carp lugs with central depression. One face (Fig. 69.1d) bears thin

white paint from the line of the nostrils to well up on the forehead; the ears, cheeks and mouth, thin red. Another (Fig. 69.2c, d) shows traces of the same treatment and there are slight evidences of white on still others. The interiors of the bowls are not fire blackened. Such was the standard type, of which we have six heads, all evidently from different vessels, and several fragments; there is one piece from a very much smaller example (Fig. 69.2a, lower right).

If we are correct in believing that the above described vessels bore three heads, there can be little doubt that they are related in some way to, and probably exercised the same function as those with three similarly placed, but smaller, heads that have been found on the south coast of Guatemala, in Mexico, Salvador, and Honduras (see Note 15). There is no evidence, however, that our specimens possessed the scoop in the rim that appears between two of the heads of those from the Rio Coyolate, Guatemala (Note 15) and from Teotihuacan (Linné 1934, Figs. 155, 156); nor do our heads have an opening to the outside. The Kaminaljuyu "rim-head" vessels are certainly older than most of the above and may, indeed, be the oldest of all.

In closing, attention may be called to the resemblance of these high, bald heads with their upturned lower lips to representations of the human head in Olmec art.

Some Mexican Figurines of the Colonial Period

R. H. Barlow

The manufacture of "*idolitos*" did not, of course, stop with the conquest, though there must have been some shift in their function. Sr. Miguel Covarrubias, who owns ten of the eleven figurines depicted in the accompanying illustration, observes that all sorts of little clay figures are sold in the markets today, for various occasions or merely as toys. In any case, it seems worthwhile publishing specimens of transitional ceramic figures as documents for the history of Mexican art and as a reminder that native civilization did not collapse operatically as the curtain closed on Cuauhtemoc.

No. 1 was purchased by Sr. Miguel Barrios Espinosa in San Pedro Tlahuac; the others are all from the Covarrubias collection and come from unascertained points in the Valley of Mexico. Permission to publish is gratefully acknowledged.

No. 1 is a feminine figure, flat in back, from a one-piece mold. She wears colonial garb and feeds a shapeless little animal with a longish tail and paws (a cat?) from a bottle (?) in her left hand. No. 2 is a male head, broken from some very similar figure. Nos. 3 and 4 are women wearing shawls. The latter is cast in the round and may be stood on its base in a kneeling position. Nos. 5 and 6 are also feminine figures from two-piece molds, hollow below so that they stand. No. 7 is flat-backed, like Nos. 1 and 2, and less Indian in style. Except for her antiquated

clothing she might seem merely a broken doll, like the exquisite little heads Nos. 8 and 9. Nos. 6 and 7 have their eyes shut, as if praying.

The remaining two figures are more problematic. No. 10 is from two molds and may be set up, but whether it represents a sinner in the stocks or a child in a high chair is not clear. In either case, the expression is one of appropriate resignation.

No. 11, made of red clay from a two-piece mold, may not even be colonial. Covarrubias has so classified it, on stylistic grounds, but if we compare it with a stone drum reproduced by Keleman (1943, Pl. 292. a) and preserved in the Museo Nacional, it is clear that the hairy face with protruding, rabbit-like teeth is the same. Furthermore, the grec about the eyes of our figure is seen in the drum to be a hand, and a hand is symbolic of the pleasure gods whose names begin with the number five, such as Macuilxochitl and Macuilpiili. The headdress of our piece resembles an inverted flower, which again connects the wearer with the gods mentioned. Whatever its purpose or period of manufacture, the figurine is unusual.

Other colonial figurines are exhibited in Copilco, and a clay head wearing a ruff was recently obtained in Ecatepec by Mr. Irving Bullock of the University of Cambridge. It is to be hoped that these and other pieces may soon be published, so as to afford a wide sampling of the style.

70.1. Mexican figurines of the Colonial period.

The Dating of Structure 44, Yaxchilan, and Its Bearing on the Sequence of Texts at That Site

J. Eric S. Thompson

The hieroglyphic texts at Yaxchilan are the most tantalizing of all Maya inscriptions. Most of them, despite their generally fine state of preservation, cannot be used with assurance, for the Calendar Round dates, fully rigged with explanatory dates, are in general adrift, bereft of the anchors of Initial Series or the fair havens of Period Endings. Until the bearings of such dates are known, the investigation of the explanatory glyphs of unknown meaning which accompany them can have but meager results.

The longest text in a reasonable state of preservation at Yaxchilan is situated in Structure 44, where it occupies three lintels and six doorsteps, and reaches a total, according to Morley, of 174 glyph blocks. Morley (1938:2:440-60) discusses this inscription at length. He expresses his certainty that it dates from the Middle Period, and states his belief that it was dedicated in 9.13.0.0.0. The decipherments which I propose differ radically from those which are published by my colleague in epigraphy and to which the reader is referred.

This spring Mr. Giles G. Healey paid a visit to Yaxchilan, largely to comply with my request for photographs of several sculptures at that site. Among them were splendid photographs of the upper step of the southeast doorway of Structure 44; these, with his wonted spirit of disinterested generosity, he placed at my disposal (Fig. 71.1).

It was immediately clear that there were serious errors in Money's decipherments of the dates on this step. Furthermore, the photographs supplied confirmation of a belief I had long held that the month

sign of the Initial Series of Lintel 46 was Kankin, not Mac. Below are given the decipherments as I see them. Those that are new readings are marked with an asterisk; the others are according to prior decipherments by Morley or Bowditch. I have omitted divisions of glyph blocks.

MIDDLE DOORWAY

Upper step A	A1-D2	9.12.8.14.1	12 Imix 4 Pop I.S.
	D8-C9	12.0	
B	C10	9.12.9.8.1	5 Imix 4 Mac
Lower step C	M1-N1	9.11.18.15.1	7 Imix 14 Zotz'
Lintel 45 D	R1-S1	9.12.8.14.1	12 Imix 4 Pop

SOUTHEAST DOORWAY

Lower step E	F'1-G'1	*9.11.3.8.1	5 Imix 9 Pop?
Upper step F	V1-W1	*9.6.10.14.15	4 Men 3 Mac
	V5-W5	*7.11.2.19	
G		(*9.14.1.17.14	5 Ix 17 Kankin) see L.46
	Y4-X5	15.15.17	
H	Y5-X6	*9.14.16.15.11	2 Chuen 14 Mol
Lintel 44 I	L'1-L'2	9.12.17.12.0	13 Ahau 3 Muan?

NORTHWEST DOORWAY

Lower step J	W'1-X'1	*9.8.0.15.11	4 Chuen 9 Xul

	O'6-P'6	3.2	
P	P'8	*9.15.0.0.0	4 Ahau 13 Yax
		12.0	
		(*9.15.0.12.0	10 Ahau 18 Zotz'
			Not repeated
Lintel 46	GA''1-G''2	*9.14.1.17.14	5 Ix 17 Kankin I.S.

These dates will be discussed in order, although I am not sure that the sequence as given above is necessarily correct. I have started with one Initial Series and finished with the other. Attention is called to the relationship with the dates of Structure 23 (Lintels 24, 25, 26, and Altar 7), the dedicatory date of which has been firmly placed by Morley at 9.14.15. 0.0 11 Ahau 18 Zac.

Dates A and B. Decipherments as first made by Bowditch. They are perfectly straightforward save that the coefficient of Mac looks like 9 instead of the required 4. Date B is found also on Lintel 25 of Structure 23. The Lunar Series with Date A does not conform to the requirements of the period of lunar uniformity, for the coefficient of Glyph C is 4, whereas in the period of uniformity it should have been 6.

Date C. The date 9.14.11.15.1 3 Imix 14 Ch'en, exactly 2 katuns and 13 tuns later, appears on Lintel 25.

Date D. Morley's restoration of this date seems perfectly acceptable.

Date E. A dubious reading. What may be the strokes at the bottom of Imix are perhaps recognizable. This date is 1 katun 6 tuns; that is, twice 13 tuns earlier than Date B.

Date F. Morley reads the day as 4 Ahau and changes the distance number, which is either 7.11.2.19 or 7.11.1.19, to 6.16.1.19 to connect with Date H, which he reads as 2 Imix 14 Mol. However, such drastic alterations of the original are not necessary. The day sign at V1 is almost certainly Men, not Ahau. The beaked nose, squarish eye, peculiar cap, and lines around the mouth, all features of Men, are quite clear. The distance number leads forward to Date G.

Date G. This does not appear here but occurs on Lintel 46 in the form of an Initial Series, all the periods of which, except the kins, are missing. The terminal date is 5 Ix and a head variant of a month sign which has a coefficient of 17. Bowditch identified the sign as that of Mac; Morley first plumbed for Muan, but later accepted Bowditch's identification. For several years I have felt that both decipherments were wrong, and that the month sign was in reality the head variant of Kankin. This identification has the following points in its favor: Firstly, the postfix is of the type found with Kankin but never with Mac. Secondly, the prefix nearly always a part of Mac in the inscriptions (but not in Codex Dresden) is absent. Thirdly, the animal's head has a pointed ear, which is typical of the head variant of Kankin but not of that of Mac. Fourthly, what remains of the Initial Series introductory glyph seems to show the two arches of the form corresponding to Kankin. The distance numbers prove the identification.

Similarly, the month part of the date on Stela 20 must be Kankin, not Mac.

Unfortunately, both the moon age (14D) and the form of Glyph G (apparently G3) cannot be reconciled with an Initial Series corresponding to 5 Ix 17 Mac. One has two choices within the possible range of acceptable dates:

G	9.14. 1.17.14	5 Ix 17 Kankin	Glyph G3	Moon age approx. 22d
G'	9.16.14.12.14	5 Ix 17 Kankin	Glyph G2	Moon age approx. 14d

The lunar data are somewhat confused. Glyph C has a coefficient of 2, for the top dot is obviously the eye so frequently placed before the forehead of the death god, yet Glyph X is the crossed-legs variant found only with Glyphs C3 and C4, so far as we presently know. Furthermore, the coefficient of Glyph D is an irregularly constructed 14, for the space which it is assumed that the bottom dot occupies is practically equal to that of two of the others. Nonetheless, there can be little doubt that 14D is carved (the moon

glyph is not Glyph E, but Beyer's shining moon variant with the eye, not a dot, in the center).

In 1937 I (Thompson 1937:72) favored the second reading, but now I am forced to conclude that the agreement thereby reached with the moon age must be discarded in favor of the first reading, one Calendar Round earlier. Whether the correct form of Glyph G or the correct moon age was of more importance to the Maya we have no means of knowing, but the earlier date fits better in the pattern of the whole text. The choice of the second would produce a reading for Date H of 9.17.10.10.11 2 Chuen 14 Mol, which would fall some time after 9.15.0.0.0, which, I believe, was the dedicatory date of this text.

Date G is 29 tuns before the date 9.15.10.17.14 6 Ix 12 Yaxkin, which appears on Stela 12, where it is safely anchored, and on Lintel 27 of Structure 24. The interval is not one generally recognized as significant, and its occurrence may be fortuitous.

Date H. Morley reads this as 2 Imix 14 Mol, but the curving strokes of Chuen are as clear as day in the photographs. Furthermore, Morley is forced to change the distance number from 15.15.17 to 15.15.6 in order to use this reading. The date as freshly deciphered fits very nicely.

Date I. I have some misgivings about the identification of the month sign as Muan. There is an eroded superfix, whereas Muan never has that detail. Furthermore, the features of the head are somewhat unlike those of the standard variations of that month sign. Nevertheless, it is probable that Morley's identification is correct. The date is 2 katuns 3 tuns before Date N.

Date J. The position here chosen is one Calendar Round earlier than that favored by Morley. The date falls 5 katuns before the Initial Series on Stela 5.

Date K. Joined to Date K by a distance number. It marks the end of 13 tuns. The same date occurs on the Tablet of the Inscriptions at Palenque, where it also was far in the past when recorded.

Date L. The reading is shaky. The month sign is 1401; the day may be Lamat. The absence of good photographs makes this decipherment uncertain. It can, however, be connected by distance numbers with surely deciphered dates.

Date M. This date does not appear but may occupy glyph blocks 0'1, P11, at present covered

with masonry. That it was intended is, I think, fairly evident from the distance numbers.

Date N. This is reached by a distance number of 4.5.12.0, which Morley changes to 4.5.17.0 so that it will fit his scheme. The date is 2 katuns 3 tuns after Date I.

Date O. This is safely tied by distance numbers to the sequence.

Date P. The very important katun ending 9.15.0.0.0 4 Ahau 13 Yax. The declaration that it marks the completion of 15 katuns is not on the visible parts of the text, but glyph blocks O'9 and P'9, where such a record would normally occur, are covered with masonry added to support the door jamb. The various katun glyphs with coefficients of 4 and 5, to the presence of which on the riser of the step Morley calls attention, might well have some connection with this celebrated date. Except for the slight overlap of Date N (cf. that of Los Higos, Stela 1), 9.15.0.0.0 is apparently the latest date in the inscription and therefore presumably the date of the monuments dedication. It will be remembered that this text shares Date B with Structure 23 and has another date (Date C), which has an anniversary, 2 katuns 13 tuns later, also on Structure 23. That building, however, has been safely dated by Morley as 9.11.15.0.0, just 5 tuns earlier than the assumed dedicatory date of Structure 44.

All in all, I deem the Calendar Round positions now assigned the dates in this text fairly secure, and certainly more logical than those proposed by my colleague. I regard it as reasonably certain that Structure 44 bears the dedicatory date 9.15.0.0.0.

In passing, I have noted various anniversaries as they may be of help in anchoring the dates of Yaxchilan. These were:

- Date J. The Initial Series of Stela 5 is 5 katuns later.
- Date N. This falls 2 katuns 3 tuns after Date I.
- Date C. The date 9.14.11.15.1 3 Imix 14 Ch'en on Lintel 25 is 2 katuns 13 tuns later.
- Date E. This is 1 katun 6 tuns (2x13 tuns) later than Date B. But the reading of Date E is not certain.
- Date G. The date 9.15.10.17.14 6 Ix 14 Yaxkin is 1 katun 9 tuns later.

Below are listed additional anniversaries at Yaxchilan, but Calendar Round positions are not certain in all cases. I give the positions I think most acceptable in parentheses but have no marked confidence in the correctness of my choices:

A	Lintel 1, etc.	9.16.1.0.0	11 Ahau 8 Zec
A'	Lintel 2, Str. 33	9.16.6.0.0	4 Ahau 3 Zotz' 5 tuns
5 tun anniversary			
B	Stela 11	(9.15.19.1.1)	1 Imix 19 Xul
B'	Strs. 1 and 42	(9.16.4.1.1)	7 Imix 14 Zec
5 tun anniversary			
C	Lintel 27, Str. 24	9.13.13.12.5	6 Chicchan 8 Zac
C'	Lintel 26, Str. 23	9.14.8.12.5	11 Chicchan 13 Yaxkin
15 tun anniversary			
D	Lintel 26, Str. 23	(9.14.12.6.12)	12 Eb 0 Pop
D'	Lintel 9, Str. 2	(9.16.17.6.12)	1 Eb, end of Yaxkin
2 katun 5 tun anniversary			
E	Lintel 40	(9.14.15.9.3)	12 Akbal 16 Uo?
E'	Altar 3	9.16.1.9.3	12 Akbal 11 Kankin
26 tun anniversary			

Dates A and A' and C and C' require no comment. They are firmly tied to the Long Count. The Initial Series corresponding to Date C' I published in 1937. Morley reached the same conclusion independently. In view of this agreement, I think the decipherment may be accepted as correct.

Date B occurs on Stela 11 but is not tied to the other dates on that monument. On the whole, Morley's placement appears the best choice. However, if that is accepted, Structures 1 and 42 were erected at 9.16.5.0.0 or even later. I see no valid reason why that should not be the case. It can hardly be coincidence that Date B' is exactly 5 tuns after Date B. Concerning the positions of Dates D and D' there is still less certainty, but I see nothing against the proposed placements. Date E Bowditch reads as 12 Ben 16 Uo; Morley, as 12 Ahau 18 Uo. The month coefficient is surely 16, the two ornamental crescents being quite plain. The transversal line of Akbal is reasonably clear in Maler's photograph, and the two circles at the top are prominent. I think the reading 12 Akbal 16 Uo can be accepted without undue reserve. Date E' is an Initial Series. Morley's painstaking decipherment of it is certain. We have already encountered a 26 tun anniversary in Structure 44. Anniversaries involving 13 tuns appear to have

71.1. Upper step, southeast doorway, Structure 44, Yaxchilan, showing dates F and H. (Courtesy of Giles G. Healey.)

been favored at Yaxchilan, presumably because they are valid not only in terms of the Long Count, but also are anniversaries in the 260 day cycle.

In suggesting amendments to a few of Morley's readings and interpretations, I may, perhaps, appear to be in disagreement with much that he has written. That, of course, is not the case. The ninety-nine sheep lie unnoted in the fold of safe decipherment, while I pursue, over the hills and dales of somewhat polemical writing, the one ewe lamb that has strayed. I would feel justifiably proud had I as large a flock safely bedded in that fold.

Morley has, perhaps, been unduly influenced by his scheme of artistic development. Dates are placed in accordance with his analysis of Yaxchilan art. He postulates an unbroken advance in artistic achievement, followed by a swift retreat. Each artist is

assumed to be somewhat better than his predecessor. Such is not, alas, the course of sculpture or of any other art, so far as I know, anywhere in the world. Did such a law exist, it would greatly simplify the work of art historians. First-rate artists tend to cluster at peaks of cultural achievement, as Kroeber has shown, but there is no evidence for a law of gradual improvement in style (assuming such a thing can be gauged), for techniques hardly enter the picture so far as Yaxchilan is concerned. Such a uniform and undeviating advance may have occurred at Yaxchilan, but it can hardly be postulated.

The same sets of Calendar Round dates occur on two different groups of lintels, one of which, Morley notes, is markedly inferior in style to the other. Consequently, he places the dates involved one Calendar Round apart, holding the interval of 52 years to account for the advance in presentation. Nevertheless, there is no authenticated case in the whole body of Maya inscriptional texts of a date being commemorated by its Calendar Round anniversary. Anniversaries in terms of the Long Count (5 tuns, 10 tuns, 13 tuns, 1 katun, etc.) are plentiful, and, so far as we know, represent the usual method of marking anniversaries in terms of the calendar. That method was followed at Yaxchilan and was common at most Maya cities (e.g., the anniversaries of 6 Caban 10 Mol at Copan). Authentic examples of Calendar Round anniversaries should surely be demonstrated before the practice can be assumed to have existed. Furthermore, Long Count anniversaries of single dates were the practice, not linked anniversaries of several dates, as are assumed for these Yaxchilan texts.

Important dates were often repeated on monuments, the dedicatory dates of which are several decades apart, but their Long Count positions remain unchanged. The same probably was the case at Yaxchilan, but the same sequence of dates would hardly be repeated five decades later without any additional dates. Therefore, from the epigraphic point of view, I think we must assume, in the absence of evidence to the contrary, that the dates repeated on these lintels at Yaxchilan occupy the same positions in the Long Count, and have approximately the same dedicatory dates. As a corollary, we can be reasonably certain that artists of the first rank and those not out of the top drawer were near contemporaries.

There appears to be no evidence that at Yaxchilan the ratio of probability of correct decipherment rises with the proximity of a date to another in the same inscription or to the dedicatory date. As we have noted, there is one distance number of over 7 1/2 katuns and another of over 4 katuns in Structure 44: in Structure 10 there is a distance number of 2.3.5.10,

and others carry the count forward another 19 tuns. On Lintel 21 there is a distance number of over 15 katuns.

It would appear probable that the positions of Calendar Round dates in relation to the dedicatory date depend largely on the functions they perform. Thus a date which serves as a determinant of the dedicatory date will almost certainly fall in the same katun; another which, let us assume, served to mark some method of lunar reckoning might well be placed several katuns in the past in order to demonstrate with more clarity the equation employed. Generally speaking, dates at some cities tend to be in the katun on which a monument was dedicated, but we have no reason to suppose that the same is true of Yaxchilan, where a different method of recording dates was generally employed, and where, as yet, few dedicatory dates have been identified. However, even if it is assumed that the people of Yaxchilan were interested in placing dates within a katun of the dedicatory date, it by no means follows that a date 2 tuns from the dedicatory date is more likely to be correct than a date or 5 tuns removed therefrom.

I think, then, that the placement of Yaxchilan dates should, for the present, be made independently of sculptural variations. Later, when more is known concerning the development of that art, it may be possible to arrange the texts at Yaxchilan accordingly. It is to be doubted that a stage will ever be reached, at which sculptures can be arranged one by one in precise order.

Anniversaries should be helpful in placing some texts, and the presence of the same or related dates in different texts should be of value in arranging a general sequence. For example, the fact that Structures 23 and 44 share a date (far in the past when each was dedicated) and one has a date that is an anniversary of a date in the other (both dates, in turn, are probably anniversaries of a yet earlier date which has not survived) hints that the two structures are of approximately the same date. The new decipherments of the text of Structure 44 indicate that this building was dedicated 5 tuns after Structure 23. Similarly, Structures 1 and 42 were probably dedicated at approximately the same time as Stela 11, with a fair, perhaps good, probability that they date from 9.16.5.0.0.

A feature of Yaxchilan texts is not only the scarcity of Period Ending dates but the even greater rarity of designations of dates as such. I have not lost hope that eventually it will be found that the priests of that city had a method of placing Calendar Rounds in the Long Count, although we have not yet perceived it. Possibly the "Ben-Ik" katuns in some way had that function.

Unfortunately, the name Yaxchilan has now gained rather general preference over that of Menche. It might be of interest to outline briefly the somewhat unsavory story of how this came about.

The modern discoverer of the ruins was Professor Edwin Rockstroh, of the Instituto Nacional, who was responsible for a deal of exploratory work along the Usumacinta, as well as in other regions of Guatemala. In 1881 Rockstroh visited Yaxchilan and named the site Menche or Menche Tinamit in honor of Bol Menche, the mythical ancestor of the group of Lacandon living in the vicinity. Rockstroh's name, therefore, had an association with the Lacandon and was supported by the general custom that the discoverer has the right to name his discovery. *Tinamit* is the general term in highland Maya for town or city. It derives from the Nahuatl but is a thoroughly naturalized Maya word.

Maudslay, who visited Yaxchilan on the recommendation of Professor Rockstroh, naturally followed the latter's designation and published his descriptions of the site under the name Menche. Charnay, who reached the ruins a few days after Maudslay, gave the horrendous name of La Ville Lorillard to the site. Mercifully, that has not survived. With the exception of Charnay, all Americanists referred to the site as Menche for the next twenty years.

Fourteen years after Rockstroh's visit, Maler first reached Yaxchilan and gave the site its present name. Maler had a pernicious habit of rectifying geographical names to conform to his very crude ideas on the Maya language. He disapproved of the name Menche, supplying it with a perfectly incorrect deri-

vation, which he then proceeded to condemn. He decided to name the ruins after a small tributary which enters the Usumacinta a few kilometers above the ruins. This stream was known as Yalchilan, and is thus given by Charnay and Maudslay, and thus appears on several maps. Yalchilan proved a hard linguistic nut for Maler to crack, even with the peculiar crackers he was wont to employ. From the Pio Perez dictionary, apparently, he learned that *chilan* was the past participle of a word meaning to lie down or stretch oneself full length. *Yal* seems to have stumped him, so he changed it to *yax*, green. Thereby he obtained the fantastic meaning 'green stones,' a reference to the color of the stones, he thought. In his own words: "Green stones. *Yax*, green; *chilan*, that which lies or is scattered about; by extension in this particular case, stones." Quite apart from the fact that *chilan* could not have the meaning he gives it, and that *yal* can hardly be changed to *yax*, the construction he proposes is impossible in Maya.

Having coined an ungrammatical and meaningless name and having unethically substituted it for that given to the site by its discoverer, Maler indulged in a few ponderous jests at the expense of the learned men who were using Rockstroh's name. Yaxchilan, misbegotten of ignorant tampering with the Maya language and an ungentlemanly disregard of the rights of the discoverer, was quickly adopted by such writers as Bowditch, Spinden, and Morley, who for the most part completely ignored the name Menche. With such honored godparents, the illegitimate word soon attained respectability; the usurper succeeded in ousting his legitimate half-brother.

The Codex of the Derrumbe del Templo Mayor

R. H. Barlow

According to the text of 1553, *Costumbres de Nueva España* (1943:1, 57) "... llegado que fue el marqués del prendimiento de naruaez a su jente le halló herido a moteçuma y mandó el marques dar fuego a todos los cues y altares que tenían y como se quemauan se caían y al caer vn cu grande hizo gran ruido y preguntando moteçuma que ruido era aquel le dixerón que auia caído el cu y de este enojo murió . . ."

In the accompanying plate we have a portrayal of the blowing up of the Temple of Huitzilopochtli, in a codex which I have provisionally baptized with a name derived from the event. The Nahuatl text refers to the Year 1 Acatl 1519, and beginning at the side of the uppermost building reads "ytecpanchan moteuczoma uei tecpa mexico tenochtitlan" ("Moctezuma's government house. The great government house of Tenochtitlan"). Below this first inscription is added "occecca yn ipilchan y moteucçoma tlacateuctli" ("elsewhere, the princely house of Moctezuma the tlacatecuhtli").

Above the second building, the one intended to represent a pyramid with steps, appears the news that it is "ycal diablo quitteq . . . q qlatique yn españoles oca mexico" ("the Devils House which the Spaniards burned here in Mexico"). At the foot of this temple we read the principal inscription: "ypan ni ce Acatl xiuitl in vallaque in españoles yn marques y uel achto ocan calaquico in texcalan yn oqu iuh mitouaya. in ya uecauh in ualnauatlatotia ciuatzintli cempoualtecatl uel chane teticpac. ynic ome ytoca tlacochcalcatl. no achto canaco iniquac yancuican quittaco tlalli yn españolesme in çan ococan mocue-

paco in uey atempa yua in uel iquac machiyaco in oyttaloque aqui que yn oquiçaco yn oyttoque nima yquac quicac yn inteyo yn moteuczoma in tlacateuctli yuan tlanauati in chialo(z)q yn ompa auh in oyaque quiçaco yciuhca (q)ualtotocaque in cenpoualteca yn aquin tlaqual [sic] yn aoquin cochiz ynic qcaquitico yn moteuczoma. otlattoq inixpa in teteuctin in tlacatecatl atliacatzin tlacochcalcatl tepeuatzin yua tlatilolco quauhtemoctzin." This may be translated: "In the year 1 Acatl the Spaniards arrived, the Marquis. Before anything else, they entered Texcalan [Tlaxcala]; at once, it was said. For some time a woman of Cempoalla, and resident of Teticpac, had come interpreting. The second [nahuatlato] was called Tlacochcalcatl; likewise from the first the Spaniards had him, when they first saw the land, when they had just come back there to the shore [following the Grijalva and Córdoba expeditions]. It was just then that it came to be known that they had been seen by those who came out [to spy], that they were spoken to. The tlacatecuhtli Moctezuma heard the news about them immediately and ordered that they be awaited there, and they [the messengers] departed, they went rapidly. They followed the people of Cempoalla, without food, without sleep so that Moctezuma might come to know. They spoke before the lords Atlixcatzin the tlacatecatl, Tepeuatzin the tlacochcalcatl, and Quauhtemoctzin of Tlatelolco . . ."

Short inscriptions occur at either side of the temple stair. On the left we read "malintzin nauatlato teucciuatl chane teticpac" ("Maliache, nahuatlato, princess, inhabitant of Teticpac"), which agrees with

Cristobal del Castillo, who states that Malinche was of Mexican parents, and had been sold by them in Teticpac, a town of Coatzacoalcos. On the right of the stair figures the name of the other interpreter mentioned in the long text: "tlacochcalcatl nahuatlato." No drawings of these interpreters appear, however; and a brief note in Spanish concludes the collection of texts which Mr. Byron McAfee has helped me to translate: "Este año començo la conquista de la tierra don fernando cortes y sus compañeros."

Another drawing of Moctezuma's government palace (Tecpan) appears in the Mendocino. The present version is rather fantastic, although the Mendocino agrees in giving the edifice two stories.

The tracing from which the plate is published was lent by Sr. Guillermo Echaniz. It will be noted that besides the page which the artist traced in toto, specimens of other year glyphs appear on the bottom margin of the tracing. At the extreme top margin appears the number 1250340 (the acquisition number of some library?), and the tracing seems to have been made years ago. Has any reader of these *Notes* further information on this codex, which remains otherwise unknown to me?

72.1. Codex Derrumbe del Templo Mayor.

Some Examples of Yeztla-Naranjo Geometric Ware

R. H. Barlow

A new type of painted pottery, corresponding closely to that from the old Tepuzteco area, was found by Mr. R. J. Weitlaner and myself in the southern drainage of the upper Balsas River (Rio de las Truchas). We published two complete pieces in *Tlalocan* (1944:1, Pl. 4) and Hendrichs published a third, from Ichcatepec, north of Balsas, in *Tierras Ignotas* (1945-1946:1, Fig. 106). To this scanty record of illustration it seems appropriate to add my drawing of four sherds which we acquired for the Instituto

Nacional de Antropología in 1944 (Fig. 73.1a-d) and a photograph of a vessel examined in Naranjo (Fig. 73.1e).

From these pieces a typology of the style may be undertaken. Decoration consists of geometric painting on a white or cream slip, and is either chocolate or red-and-black. The major design area is exterior, but the inside rim bears a simple pattern. Two forms of tripod bowls appear: those with hollow legs resembling the end of a broom handle, and those with ring-

73.1. Sherds and bowl in Yeztla-Naranjo style from El Naranjo, Guerrero (scale of sherds about $\frac{3}{4}$; bowl 13 cm across top).

shaped legs. The former are decorated with designs somewhat like exaggerated cigar-bands. In the few pieces available, certain elements are repeated: a diamond pattern (Fig. 73.1b, d), a boxlike maze (Fig. 73.1d; Hendrichs 1945–1946:1, Fig. 106; *Tlalocan*, Pl. 4, upper left), and a spiral (Fig. 73.1e; *Tlalocan*, Pl. 4, upper left). Dots are used singly or in rows (Fig. 73.1d, e; *Tlalocan*, Pl. 4, upper right).

Ring-shaped supports or variants thereof are found in Nicoya black-line ware and in red-lip ware and Curridabat ware from Las Mercedes, Costa Rica (Lothrop 1926:1:224, 2:clxvii, clxxiii); in Estanzuelas red-on-buff in eastern Salvador (Longyear 1944, Pl. VIII, 31); and in the Soncautla complex, Tres Zapotes (Drucker 1943b, Pl. 24). Additional data on distribution would be welcome.

The Treble Scroll Symbol in the Teotihuacan and Zapotec Cultures

Horace Neys and Hasso von Winning

There exists in the art of Teotihuacan an ornament consisting of three simple scrolls, which form a whorl. This design has also been used by other peoples, especially the Zapotec, and by all of them in such a particular way that it must be taken not as a mere decoration but as a symbol.

The simple scroll usually is repeated in a horizontal band or as a frame and represents water. We think that this trilobe derives from the horizontal scroll band and is also a sign relating to water.

Various appearances of the treble scroll will be described. All, if not stated otherwise, were purchased in Azcapotzalco, and are in private collections. They appear, therefore, to belong to the Teotihuacan culture.

The first example shows the treble scroll incised on both sides of two shoe-shaped vessels (Fig. 74.1a). On a third shoe-shaped vessel of the same size we find on the point of the shoe not the scroll but a sign representing four drops of water, arranged at right angles and painted in red. As no other symbols of this particular type or any other are known to us on vessels of this specific shape, we take it that the four drops and the treble scroll are somehow related.

The fact that these water symbols appear on shoe-shaped vessels which are unusual at Teotihuacan but frequent in the Zapotec culture might point to their having been used for the same religious ceremonies, imploring rain.

The treble scroll occurs also on a fragment of a well polished, red incised bowl (Fig. 74.1c). Unfortunately the design is not complete and the meaning

of the three lines emerging on the right side of the cartouche is not clear. The scroll band on the top is frequently found on this type of vessel and represents water.

Our surmise gains in certainty with a brown vessel in the museum at Teotihuacan, where the same treble scroll motif is incised, but this time raindrops are pendent from it, the whole design being framed with fades (Fig. 74.1b).

Figure 74.1e shows another typical Teotihuacan vessel. On both sides there is a treble scroll decoration as the center of a dagger-shaped instrument which is slightly curved at one end. The straight end is decorated with close-set, parallel lines; the curved end is decorated with irregularly placed finer lines, which might represent water flowing outwards from the whorl. This vessel has broad lines of stick decoration on the neck.

Yet again we find the same design on potsherds of a spherical jar, depicted in red-brown-on-black, outlined by incision (Fig. 74.1d). The middle whorl, however, is larger, the straight end has the same vertical lines, but the fine lines on the other end are missing, showing instead one drop falling from its curved point and three more drops falling from the center whorl. This design and the one described before give the impression of being representations of a ritual object in which the three scrolls are incorporated, used in ceremonies having to do with witchcraft for obtaining abundant rain.

On the mural paintings at Teotihuacan (Gamio 1922:1, Pl. 29) we see a row of similar objects (Fig.

74.1. (a) Shoe-shaped vessel, dark brown, polished; incised before firing (scale = 2/3; Coll. H. Neys); (b) treble scroll design incised on brown jar (scale = 2/3; Museo Regional de Teotihuacan); (c) fragment of a cylindrical bowl, polished red; incised white clay was soft (scale = 2/3; Coll. H. Neys); (d) design in red-brown-on-black, outlined by incision, on fragments of a spherically shaped vessel (scale = 1/3; Coll. H. Neys); (e) yellow jar of typical Teotihuacan shape; design incised (scale = 2/3; Coll. H. Neys).

74.2a), which after comparison with the above mentioned signs we also consider as instruments for witchcraft. Although somewhat different in shape, the drops fall from their points, which with the channel leading out from the center leave little doubt as to their identity with the objects in Figure 74.1d, e. Curiously enough, the drops are painted red. We do not know what is meant by the design divided in five parts, which seem to hang from the square-shaped center, but possibly it might represent a current of water as appears in front of the mouths of serpents, tigers, and birds in Teotihuacan. These bands with rounded ends do not resemble feathers.

Our assumption that these instruments for witchcraft were actually held in a hand is confirmed by a similar object depicted on the newly discovered wall paintings at Tepantitla, Teotihuacan (Fig. 74.2d). The human hand is clearly distinguishable and the falling drops again indicate a relation to water.

The general impression one receives is that these objects were used in a ceremony rather like the present-day holy-water sprinklers in Roman Catholic ritual.

This leads us to assume the sculptured ornament in Figure 74.2c to be an instrument of the same kind. It appears behind the headdress of the stylized Tlaloc faces on the Quetzalcoatl pyramid at Teotihuacan. (The reproductions in vol. 1 of *La Poblacion del Valle de Teotihuacan* do not show this detail. We have therefore used the photograph on p. 72 of *L'art vivant au Mexique*. What might be the handle of the instrument is hidden by the headdress, but something like a knob is shown on the left side. The right end appears wavy and might represent feathers tied to the handle. In this case it is not clear what function this instrument might have had, although its presence together with a serpent and a Tlaloc-like head suggests a relation to water.

Since the treble scroll symbol is rare and is even less frequent in Teotihuacan than in Azcapotzalco, a few more examples will be described.

Linné (1934:125) depicts a small collection of clay stamps from Teotihuacan, one of them showing

74.2. (a) Detail from a fragment of a mural painting in the Museo Regional de Teotihuacan (after Gamio, *La Poblacion del Valle de Teotihuacan*); (b) fragment of an adorno that had been attached to a vessel; inside the six-pointed star, a treble scroll motif in relife; natural size (Coll. H. Neys); (c) detail of the masked heads of the Quetzalcoatl pyramid at Teotihuacan; (d) detail from the frescoes at Tepantitla, Teotihuacan; (e) relief plaque with three scrolls, previously used as an applied motif; natural size (Coll. H. Neys); (f) detail of Stela 7, Monte Alban (after Caso); (g-i) details of Stela 8, Monte Alban (after Caso).

a treble scroll. Their smallness makes it possible that they had been fastened to a piece of wood to make them handier. The use of these small round clay stamps, which Linné reproduced in his Figures 221, 225, and 227, is not clear. They might have been employed for decorating tiny loaves of bread in ritual ceremonies, for which in this case a wooden handle would not have been necessary. Remarkable, however, is the great variety of representations on the stamps or seals: heads of Xipe Totec, Tlaloc symbols, animal heads (eagle, deer, and rabbit), human figures holding a scepter or covered with an animal mask, representations of the Fat God, flowers, etc., some of them resembling the designs on spindle whorls, suggesting that the clay stamps too might have been given to the dead as an indication of their membership in a certain clan.

Again, the treble scroll appears in the center, of a star, together with a curved object, molded on a motif applied on a fragment of a brownish red vessel (Fig. 74.2b). Both the six-pointed star and the curved object are not typical in Teotihuacan, but we find the latter in connection with a flower on a slab with a Tlaloc face (Gamio 1922, Pl. 131b, upper right and left sides).

In relief, the treble scroll is found deeply incised on small round plaques which are slightly hemispherical and which have been used as applied motifs. The scrolls, however, do not begin in the center of the circle but start from the circumference (Fig. 74.2e).

The Aztec did not adopt the treble scroll symbol, but it is found in the Zapotec culture. One of the so-called funerary urns shows these round, incised plaques on the shoulders of a seated figure, probably representing the God of the Harvest (Linné 1938:121, Pl. 13).

Stela 7 of Monte Alban shows the symbol in question as the lower part of a glyph (Fig. 74.2f.). On top of this glyph appears another glyph expressing a date; both are placed in front of a priest (Caso 1928:86, 145).

Our symbol appears three times on Stela 8 (Caso 1928:88). Once it forms the center of a hieroglyphic expression, the top of which is clearly the day sign J (Fig. 74.2i). Caso refers to it as a "triple espiral." The second representation is on the side of the same monument, interpreted by Caso as "... hay sobre un cerro una figura sentada. Del cerro sale una voluta,

quizá una planta, y en medio lleva su nombre jeroglífico expresado por tres espirales que se juntan por sus extremos" (Fig. 74.2h). In the third representation the treble scroll again seems to be connected with two more glyphs (Fig. 74.2g).

Also, a carved stone plate on Montículo J at Monte Alban depicts the treble scroll in connection with other glyphs, and the symbol in question is further to be seen on the base of a Zapotec urn, surrounded by the stylized *sign* for mountain (Linné 1938:136, Pl. 19).

On the mural paintings in Tomb 104, Monte Alban, the treble scroll appears to be decorated with the typical Zapotec jaw-like adornments. Compare Glyph A (Caso 1928, Fig. 3, I-III) and Glyph J (Caso 1928, Fig. 13, I-IV bis). Two tied objects are depicted a little higher on both sides. It seems that the priest to the left, whose attitude indicates the performance of a ritual action, has to do with the arrangement of signs in front of him, mentioned before.

That our symbol appears on a vessel found as far as Chiapas is shown by Blom and La Farge (1926-1927:232), who depict a bowl on which it appears in black as a single motif, on what seems a basket-weave background.

We cannot prove, however, that these representations of the treble scroll in Zapotec art have been used to express the same symbol we think they did among the Teotihuacan people. The examples of the treble scroll in Teotihuacan art point to a connection with water, thus implying an intimate relation to this element. (It might be the symbol for "rain-bringing wind" or "cloud.") Whereas the appearance of the same symbol among the Zapotec is related to chronological glyphs, to the stylized sign for mountain, and to other glyphs which have not yet been deciphered. Considering the exchange of cultural elements between the peoples of Teotihuacan and Azcapotzalco and the Zapotec, it is not surprising that they should have used this particular symbol contemporaneously, but it is difficult to determine where it originated.

It is interesting, however, to note that we find the treble scroll symbol on the Montículo J at Monte Alban and that Caso (1938:11) attributes it to the epoch of the Danzantes, or the one immediately following, thus showing its extreme antiquity and possible origin.

The Book of Chilam Balam of Ixil

Ralph L. Roys

Most of the so-called Books of Chilam Balam are essentially almanacs. They are written in the Maya language of Yucatan and in the European script adapted by the missionaries to express the sounds not found in Spanish. Brinton (1890:257) tells us that "in whatever village it was written, or by whatever hand, it always was, and to-day [1890] still is, called The Book of Chilam Balam." Crescencio Carrillo y Ancona (1937:12) had already made a similar statement, so no doubt this was true during the middle years of the nineteenth century.

At the present time the term appears to be little known. Indians and village schoolteachers, whom I have asked, said they were unfamiliar with it; and one schoolmaster stated that manuscripts of this character are called *lunarios* ("almanacs"). At Mani the name of the prophet Chilam Balam is still remembered, and I was shown the alleged site of his home near Cabalch'en cenote.

How extensively such manuscripts were called Books of Chilam Balam in colonial times seems uncertain. During the first half of the nineteenth century Pio Perez compiled a book of extracts from manuscripts of this sort, most of which he found at Mani. The title, which is "Chilam Balam," would seem to indicate that this was the general name of the larger number of his sources, but it is doubtful whether he wrote this title himself. One of the subtitles is "Código Perez; Extractos de varios ejemplares del 'Chilam Balam'" and this is certainly written in the hand of Bishop Carrillo, who had the book for a time in his possession. Nevertheless, there was

evidently at least one old manuscript at Mani which bore this title. On page 137 of the Codex Perez we read "Fin del libro," after which Carrillo has interpolated the words "de Chilam Balam." The passage continues in Pio Perez's writing: "Hasta aquí termina el libro titulado de Chilambalam que se conserva en el pueblo de Mani en poder del maestro de Capilla y yo pongo las notas a los sucesos que refiere." This was probably the original title of this eighteenth-century manuscript, but the document itself has disappeared.

The Tizimin manuscript, which Carrillo named the Código anónimo, bears the title "Chilam Balam, Codice Tizimin, and the Chumayel, Codice Chumayel, but both of these designations are in Bishop Carrillo's hand. The Kaua manuscript is entitled "Chilam Balam. Lunario ó Winalté," but I do not know whether or not this is in the same hand as the body of the book. "Winalté," or *uinalte*, is probably the Maya equivalent of *lunario*.

In the Tizimin and Chumayel we read of a certain holy book of katun prophecies which existed in very early colonial times in the Bacalar region. This is variously called an *anahte* and a *reportorio* (another word for almanac). Since reliable sources elsewhere explain the *anahte* as a hieroglyphic book of prophecies, these references suggest that the colonial Maya sometimes designated certain hieroglyphic manuscripts as *reportorios* (Avendaño y Loyola 1696:67; Chilam Balam of Tizimin 1870:29; Roys 1933:147).

The Book of Chilam Balam of Ixil does not mention the name of the Maya prophet for whom it has

been named, but other similar Maya manuscripts include prophecies ascribed to this famous seer, who lived in pre-Spanish times and was believed to have foretold the coming of the Spaniards. The Ixil manuscript contains little of the old native lore that is not more completely covered in some of the other Books of Chilam Balam. It is chiefly valuable as evidence of the acculturation of the Maya during the eighteenth century. This in itself is important in any appraisal which we make of the historical information that has come down to us in other native sources which were compiled and edited during the same period, although much of it was no doubt taken from earlier manuscripts.

Tozzer (1921b:190, 218–19, 258) has described parts of the Ixil; and Juan Pio Perez (Codex Perez 1837:171–72, 171–76) has copied a few pages of the manuscript, which he describes as follows:

“The following wheels and explanations are copied, from an old memorandum-book found in the town of Ixil with part of an almanac in the same style as the preceding ones, and the predictions for the months are likewise similar to the first ones copied in this book [Codex Perez]. [There are also] a collection of medical prescriptions (*recetario*) for the plants of the country and some translations from the Bible about the creation of the world and the history of Abraham. The collection of prescriptions is not worthy of credit, since among its many false statements is one to the effect that it was written by a Moorish slave of the Cid. Its language is a mixture of Maya and Spanish (*amestizado*).”

Immediately preceding this description are some Maya prophecies which Perez copied at Ticul in 1837, so it seems possible that his extract from the Ixil manuscript was also made about this time.

Until recent years the Ixil has been available only through extracts. Besides that made by Pio Perez, other portions extracted by C. H. Berendt are in the Library of the Museum of the University of Pennsylvania, and still another partial copy has been reproduced by William Gates. For the present study I am indebted to Dr. S. G. Morley, who obtained a photostatic reproduction of the original now in the National Museum of Anthropology at Mexico City.

On the second page of the Ixil, 1701 is given as the current year (“Hele tu habil 1701”), so at first sight this would appear to be the date of the manuscript. The chronological errors, however, which occur on this page are such as to suggest that a later native scribe copied the passage from an older book without fully understanding the subject matter. Moreover, the character of the work as a whole is so similar to that of the Book of Chilam Balam of Kaua,

which dates from the last decade of the eighteenth century, that I believe the Ixil was compiled about the same time.

The first four pages of the manuscript (photos, 1b–3a) are devoted to Maya chronology. On the first of these are the two so-called wheels, each accompanied by an explanation, which have been reproduced by Bowditch (1910:328). The larger circle is stated to represent a katun of thirteen years. This is something very different from the usual meaning of the term, which ordinarily indicates a period of 7200 days, or approximately twenty years. Several of the colonial Maya writers, however, have explained it as a twenty-four year period, thereby causing considerable confusion in the minds of later investigators. The smaller wheel shows the order of the four year bearers and ascribes each to one of the cardinal points.

On the second and third pages are discussions of the bearers of the uinal (a twenty-day period) and the year, as well as an explanation of the alleged thirteen-year katun. These are followed by lists of the uinal names and day names. Each of the latter is accompanied by a face, suggesting that the days are personified. Over that for the day Ahau is a crown, since the name means “ruler,” and over those for Kan, Muluc, Ix, and Edznab are crosses. The first three are year bearers, so presumably the fourth cross should be over the remaining year bearer, which is Cauac and not Edznab.

On the fourth page is a garbled account of the “Burners.” These have been discussed for the past century, but their significance has not yet been satisfactorily explained (Stephens 1843:1:448–49; Bowditch 1910:218; Roys 1933:118). A more accurate account of the days on which these phenomena occurred is to be found in the Book of Chilam Balam of Tizimin on page 38.

The only other passage in the Ixil that is purely Maya in character is a paragraph (photo 17b) devoted to the native astrology and calendrical divination, of which we know so little. Sahagun (1938:1:372) condemns severely the Mexican system of divining by days, claiming that it is not based on natural phenomena like European astrology. Among the Maya, however, it seems evident that this manner of divination was sometimes related to the heavenly bodies.

In the Ixil manuscript the day 1 Kan is associated with *ah yzam ti can* (“Ah Itzam in the sky”), a bird called *ix kokta*, and a tree named *chac imix che*. *Itzam* means a lizard; possibly the sky lizard portrayed in the Maya picture manuscripts is meant. *Ix kokta* is probably intended for the *ix kokobta*, or thrush; and apparently the *chac imix* the is a mythical tree (cf. Roys, *Chilam Balam of Chumayel*, pp.

64, 100). The day 2 Chicchan is similarly associated with the *tzab ti can*, or “rattles of the snake constellation in the sky,” which has been identified as the Pleiades and a part of one of the thirteen signs of the native Maya zodiac (Motul Dictionary; Spinden 1924:55). It is further explained that “this planeta” is the mutil for people according to the day of the uinal on which they were born. In a Chumayel prophecy of the coming of Christianity we read: “You shall see the mut surmounting the raised wooden standard (cross).” In the dictionaries mut is defined as “news, information, reputation, rumor” and also as a certain bird. In the Book of Chilam Balam of Kaua, what appears to be either a scroll, or possibly a highly conventionalized bird, surmounts the cross over a katun wheel immediately preceding a passage similar to the one under discussion. To the Maya the cross was a conventionalized tree, and the bird surmounting a stylized tree is a feature common to both Maya and Mexican art (Roys 1933:167, 170; Kaua MS., p. 10; Tozzer 1921b:123). It seems evident that *mut* means augury or portent here, and I surmise that it was symbolized by the figure of a bird. Similar auguries for Kan and Chicchan, as well as for the remaining eighteen days, are recorded in the Kaua MS. (pp. 11–12, 14, 21–22) and Codex Perez (p. 94) and have been published and translated by A. Barrera Vasquez (1943).

A very considerable portion of the Ixil manuscript contains material which is essentially Maya but is modified by European ideas. Here we find a feature common to most of the Books of Chilam Balam, although it does not occur in the Chumayel. It is a correlation of the European and native calendars during nine months from January 1 to September 30. This includes the native ritual period of 260 days, which covers every possible combination of the twenty Maya day names with their thirteen coefficients.

For each day of the European month the number and dominical letter are given together with the corresponding Maya day name and its coefficient. Sunday, January 1, is the Maya day 10 Oc. Nearly every day is characterized as *utz* (“good”) or *lob* (“bad”), and in many cases other observations follow. Quite a number of these are recognizable as weather predictions, prognostics of sickness or death, or indications whether the day is a favorable one for various activities such as beekeeping, planting, hunting, etc. Others, however, are difficult to translate. Sometimes apparently they refer in obscure language to certain omens. Then there is also an attempt to fit the “Burner” items into this calendar, but it betrays a lack of understanding of the chronological pattern indicated in the Book of

Chilam Balam of Tizimin, written possibly half a century before.

In the Ixil, as in Landa’s calendar, the Maya year commences on July 16, and certain days are designated as beginning the uinals, or Maya months, of twenty days each; but the uinal bearers for these portions of two Maya years fall on Imix and Cimi instead of Kan, Muluc, Ix, or Cauac, which are the regular gear and uinal bearers, as shown on photo, 1b. It is difficult to account for this apparent error, which occurs in the similar calendars of other Books of Chilam Balam, since it is plain from other passages in the same manuscripts that the eighteenth-century Indians were still well aware of the correct year and uinal bearers.

Few saints’ days or Church festivals are noted in this calendar, and aside from its value as a correlation, it seems obvious that its main purpose was to record the prognostics and other comments which we have discussed. Although the Ixil correlation includes only nine European months, in other calendars of the same sort covering the entire year we find the same comment recurring on the same Maya day of the following series. Consequently it is evident that these observations are based on the day name with its coefficient, which determines its position in the 260-day cycle.

It is of interest to note that the late colonial Maya were still so concerned with the old ritual period at a time when they were becoming confused over their annual calendar. It is perhaps as though Japanese conquerors had imposed their own calendar upon us for a long time, but we should probably still think of current time in terms of the European week days.

Another feature, which represents a mixture of Maya and European ideas, is the medical treatise entitled “*U libroil dzaaccob*” (“book of remedies”), which fills the last twenty-seven pages of the manuscript (Photos 31a–44): These prescriptions are ascribed to a Moorish physician who had been a captive of Ruy Díaz de Bivar, the Cid Campeador, in spite of the fact that they are largely Maya in content. They do, however, contain a considerable number of European remedies, and a good many names of plants and diseases are given in both Spanish and Maya. Some European remedies are prescribed in most of the Maya medical manuscripts that have come down to us (Roys 1931), but in the Ixil, Spanish influence is especially strong. Besides the cures for diseases and other complaints, there are receipts for treating wasp and scorpion stings, blisters, hiccough, and falling hair, determining sex before birth, killing lice, cleaning grease spots, and preserving lard.

The remainder of the Ixil manuscript, comprising over half of its eighty-eight pages, is filled with

Maya translations of European material, some of it evidently taken from the Spanish almanacs of the time. On two pages (Photos 3b–4e) are diagrams of eclipses of the sun and moon followed by an explanation of the latter from the European point of view and contradicting the Maya belief that the moon was bitten or eaten (cf. Roys 1933:86–88).

The next twenty-four pages (photos 4b–16a) contain a European almanac, although all the narrative material is translated into the Maya language. On alternate pages we find a Catholic calendar and the twelve signs of the zodiac with explanations. In the former a page is devoted to each month, giving the epacts, dominical letters, and numbers of the days. Except for a few Church festivals, the saint for each day is named. This was obviously useful in selecting names for children as well as for religious observances. This calendar begins with November and ends with October.

The treatise on the zodiac is not correlated with the calendar, for it begins with Aquarius and ends with Capricorn. On each page are the picture and name of the sign and the name of the corresponding month. For Aquarius the discussion is somewhat as follows:

- The number of stars in the sign (42).
- The number of days in January.
- The number of hours of the day (9) and of the night (15).
- The day of the month when the sun enters the "house of the sign" (January 20).
- The parts of the body which are under the "lordship" of the sign.
- A characterization of the person born under the lordship of the sign.
- Activities recommended during this period.

The number of hours given for the day and night suggests a somewhat higher latitude than that of Yucatan, where the time between sunrise and sunset in January ranges from 10 h. 51 m. to 11 h. 9 m. (Espinosa and Espinosa 1928). For the days when the sun enters the first six signs recorded, which are given as January 20, February 19, March 11, April 11, May 21, and June 21, the Ixil wavers between the customary dates and the system employed in the Book of Chilam Balam of Kaua. In the latter they are given as January 11, February 13, March 11, April 11, May 12, and June 12.

Following the last page of the Catholic calendar we find (Photo. 16b) a diagram of the mediaeval conception of the cosmos: Here is a series of concentric circles showing *luum* ("the earth") in the

center and around it the crystal spheres. In the Maya explanation the latter are called the "eleven layers of the sky." In order from the center they are named Luna, Mercurio, Venus, Sol, Marte, Iupiter, Saturno, Firmamento, Christalino, Primer mobil, and Cielo empireo.

Overleaf (Photo 17a) is a correlation of the months with the signs of the zodiac and an explanation involving the use of the golden number. The chart is stated to be for the use of physicians. Some pages farther on (Photos 24b–26) are a number of tables, principally intended for the purpose of correlating the moon with the signs of the zodiac. The writer was evidently concerned with zodiacal anatomy, for on the last of these four pages is a chart or table ascribing each sign to a part of the human body and followed by this notation in Maya: "A record of where the sign is seated in the human body. It is dangerous to bleed it, if the moon is in the house of the sign which is seated in a man's body." This, of course, is the ancient warning against surgical treatment of any part of the body while the moon is passing through the corresponding sign.

So far as the colonial Maya were concerned, surgery probably meant bloodletting in most cases. This was practiced by the Maya in pre-Spanish times. Landa (1941:112) tells us: "The sorcerers and physicians performed their cures by bleedings of the parts which gave pain to the sick man." We know little of the technique of this practice in the sixteenth century. The Maya verb "to bleed" is derived from the word for flint (*tok*), but the lancet itself was called *ta*. In one of the colonial Maya medical manuscripts we find details of which parts of the body to bleed for certain complaints, but it is hard to tell how much of this information was drawn from European sources (Roys 1933:29–30). For bleeding in modern times the native medicine men employ a fragment of glass, flint, or obsidian attached to a small stick, and sometimes the fang of a rattlesnake. One patient has reported that during his illness 250 punctures were made in his legs alone (Redfield and Villa Rojas 1934:172–173, 233). In pagan times bloodletting was possibly as much of a religious rite as it was a therapeutic practice, even in case of illness. People frequently drew blood from themselves, especially from the ear, tongue, and virile organ, for sacrifice to the gods.

The Book of Chilam Balam of Ixil contains no Maya chronicles or historical narratives such as we find in the Mani, Tizimin, and Chumayel manuscripts, and the katun prophecies with their wealth of historical allusion are also missing; but in the place of these features we find two chapters of Sacred History. The first (Photos 22b–24a) begins with the

rule of Nimrod in Shinar and the building of the tower of Babel, and it ends with Abraham's sacrifice of the ram in place of his son Isaac. Some attention is paid to Biblical chronology, and Berossus is cited in connection with the age of the world at the time of these events. A number of the details, which are not in Genesis, appear in Josephus; but others, like Abraham's refusal to worship the Chaldean gods, are to be found in neither. I surmise that the narrative was taken from one of the early Church writers, possibly Eusebius. In the Ixil manuscript this account is evidently presented as a separate narrative, for a short concluding paragraph connects Abraham with the rulers of Jerusalem, and the episode of Isaac and the ram is compared with the Crucifixion. I surmise that the translation was made by a Spanish missionary, who was well versed in the Maya language.

The second Biblical narrative (Photos 27a–30b) begins with the burial of Jacob. It tells of the flight from Egypt, the journey to Sinai, the death of Moses, and the fall of Jericho. The concluding paragraph contains a brief summary of Jewish history down to the birth of Christ. Here, as in the preceding narrative, are chronological data and other details that are not in the Old Testament. One example of the latter is the story of the angel Michael, who appeared, sword in hand, to Joshua with instructions how to accomplish the destruction of Jericho.

From the photographs the Ixil manuscript would appear to consist of two different brochures, but in both the handwriting is either the same or very similar. The second part (photos 22a–44) contains only the second Biblical narrative and the "Book of Remedies."

I have already remarked on the similar character of the Books of Chilam Balam of Ixil and Kaua. Both, on the whole, pay more attention to European than to Maya ideas; but the latter is much more voluminous, since it consists of 282 pages and is wider in scope. It contains more information from European sources than the Ixil, but the same is true of its content of Maya lore, as we shall see.

The material on European astrology is more complete in the Kaua. Whereas the Ixil deals principally with the zodiac, the Kaua includes discussions of the planets and their relation to diseases, medicine, and surgery. Here also is an illustrated Maya translation of a part of the Spanish romance of the Doncella Teodora, consisting largely of dialogues on astrology. There are treatises on the proper European months for bleeding and purging, propitious days for merchants, and predictions for the years according to the days of the week on which they begin. Among the many other passages written in Maya but relating to European culture are prayers, a discourse

on the Mass service, and an account of the creation of the world. We find a few Latin prayers, and several passages are written in Spanish. One of the latter is a dissertation on astronomy; another, strangely enough, is an explanation of Maya chronology.

Most of the native lore in the Ixil is also to be found in the Kaua manuscript. The latter, however, contains several complete accounts of the omens associated with the twenty Maya day names, the Maya dates on which the *tuns* (360-day periods) would fall during the years 1797–1824, a part of a farmer's almanac, and a series of thirteen *katun* prophecies (cf. Roys 1933:183–185). More than a third of the Kaua is devoted to medicine, but, as in the Ixil, this includes a number of European remedies. The precise date of the Kaua is hard to determine. I have placed it in the last decade of the eighteenth century, because the dates 1789 and 1793 are associated with quotations from Spanish almanacs apparently of recent date. On the last page the writing is faint, but the names of two men and the town of Kaua appear to be associated with the years 1823 and 1830, and I take these men to be later owners of the book.

It seems obvious that the compiler of the Ixil manuscript was more concerned with European lore of the sort found in the contemporary Spanish almanacs than with the older native traditions and customs. His treatment of the latter indicates that many people by this time were losing interest in Maya science and chronology and forgetting things that previously had been more generally known.

Such forgetfulness, however, was not everywhere the case. The Book of Chilam Balam of Chumayel, which was compiled as late as 1782, shows that there was still a class of people who were interested in the old traditions and prophecies and a native writer who had some understanding of his subject, since we do not find in his book the theory of a twenty-four year *katun* so prevalent in most of the other Books of Chilam Balam that have come down to us. Here, it is true, there is a certain amount of European material, but by far the greater part of the book is composed of rituals, catechisms, historical narratives, and some prophecies which are essentially Maya in character, although some of these passages contain an admixture of European ideas. This does not necessarily mean that Don Juan Josef Hoil, the compiler, was not a good Christian. There is some evidence that his son became a Catholic priest and was curate of an important Indian parish in a suburb of Merida (J. Martinez Hernandez, *apud* Roys 1933:8). A still sharper contrast to the Ixil is offered by the book of medical incantations known as the Ritual of the Bacabs. The last page is written on the back of a printed indulgence dated 1779; but in spite of this

late date the manuscript is almost entirely pagan in character. From its language it would appear to be a careful copy of a much older book.

That part of the native culture which is represented by the colonial Books of Chilam Balam appears to have declined seriously after the end of the eighteenth century, with the exception perhaps of some of the medical literature. The Book of Chilam Balam of Tekax, which bears the date 1833, much resembles the Ixil manuscript. Here, however, Thompson has called my attention to the circumstance that in the correlation of the Christian and native calendars only the names of the Maya dates are given, and their coefficients, which had formerly been considered so important, are omitted. The days are characterized as "good" or "bad," but the other Maya prognostics and observations are no longer recorded. The Book of Chilam Balam of Nah, dated 1857, seems to be a copy of the Tekax manuscript, although a careful comparison might disclose some differences.

Except perhaps for the medical prescriptions, among the modern Indians of Yucatan much of the Spanish and most of the Maya lore recorded in the Books of Chilam Balam are either of little interest or have been forgotten, although some of the school-teachers say that a number of manuscripts of this character are still preserved in the Indian towns and villages. Some of these apparently contain katun prophecies, for, one informant, who seemed unfamiliar with the modern literature on the subject, said he had seen lunarios which contained a passage about the *jefes* ("chiefs"), probably referring to the name of the day Ahau, with which such a prophecy usually begins. The reference could apply equally well to the native chronicles, it is true, but these are much rarer in Maya literature than the prophecies.

The native religion has not, however, fallen into oblivion to the extent that the decay of the Chilam Balam material would seem to indicate. Prayers and offerings are still made to the bee gods, the patrons of the hunt, the rain and wind gods, and the other protective deities of forest and field. These ceremonies are essentially pagan, but they are affected by the Spanish influence to which the Maya have been subject for the past four centuries. God and the Trinity are frequently invoked, and some of the native deities have taken on the names of Christian saints. Actual idolatry has almost completely disappeared, but in the independent villages of Quintana Roo the

cross is personified and has become an oracle (Villa Rojas 1945:20–22). Gann (1918:46–47) and Thompson (1930:115–118) have published prayers from British Honduras; and Redfield and Villa (1934:339–56) have furnished us with a considerable body of ritual material from Chan Kom in northern Yucatan.

None of these ceremonies has as yet been found recorded in the colonial Maya literature, although it is possible that some of this material was put into writing and has been kept concealed. It may be only by a fortunate accident that the still more pagan Ritual of the Bacabs has come to light. I have found people very reticent about the comparatively innocent *lunarios*.

It is difficult to account for the disappearance of the culture recorded in the Books of Chilam Balam, while the old religion was still flourishing. Any satisfactory explanation would require a fuller knowledge of colonial Maya society than we now have.

The Quetzalcoatl-Kukulcan cult of the ruling class had been introduced from Mexico some centuries before the arrival of the Spaniards, but it disappeared soon after the conquest. Idolatry, which according to native legend was also a Mexican importation, persisted stubbornly for a long time in spite of unremitting efforts by the missionaries to extirpate it (cf. Thompson 1938:593–594). After the end of the seventeenth century, however, we find few, if indeed any, complaints of this practice. The katun prophecies evidently continued to be considered of importance, not only by the limited number of literate natives who made new copies of them from generation to generation, but also by many other people, for in 1668 the flight of numerous Indian families to the forests was ascribed partly to a prophecy resembling one of those in the Books of Chilam Balam (Scholes and Roys 1948).

The numerous copies of these prophecies and the prognostics associated with the Maya day names would indicate that both were regarded seriously until the end of the eighteenth century. Possibly they lost their popularity because of a growing interest in European astrology; but except for the Maya manuscripts, we have no information about the spread of this lore among the Indians generally.

What seems fairly obvious is that the native medicine and the worship of the patron deities of rural activities were the two features of Maya culture which were most firmly rooted in the native consciousness.

The "Tortuga" of Coatlan del Rio, Morelos

R. H. Barlow

The accompanying figure represents a monolith which stands in the plaza of Coatlan del Rio, Morelos. I am obliged to Dr. Robert West of the Smithsonian Institution for the photographs and the opportunity to visit the monument.

In Coatlan, which lies on the edge of the Chontal de Guerrero zone, the monument is assumed to be a turtle, but it seems more likely to be a composite of giant phallus and articulated animal. In the upper figure what appears to be the prepuce is on the right and the animal's claws are at the left. Below, the monster is clearer: it seems to rest on its back, with two claws reaching up and grasping two discs which at first glance seem to be eyes. The real eyes of the animal, as well as its beak, are visible in the lower left-hand quarter. An X or cross appears on the belly of the animal.

Neither the subject nor the style is readily identifiable. Because of its size, it could not easily be turned over, and if we judge by the supposed phallic part, it seems to rest in its original position.

Various versions were given of its origin. An ex-Presidente Municipal, however, assured us that he had brought it himself, about 1933, from "la capilla" in the "llano de Michapa," by truck.

The people of Coatlan have likewise restored (with cement) an indifferent sculpture of a serpent and set it up in the plaza as a sort of guardian spirit.

Drawings of Tajumulco Sculptures

Antonio Tejeda

Illustrated supplement to *Excavations at Tajumulco, Guatemala*, by Bertha P. Dutton and Hulda R. Hobb (1943).

During the winter of 1938–39, the School of American Research and the Museum of New Mexico carried on archaeological excavations at the small ruin site of Tajumulco, Department of San Marcos, Guatemala. A report on that work, *Excavations at Tajumulco, Guatemala*, was published as Monograph 9 of the School of American Research, November 1, 1943.

On seeing some of the cultural material and photographs sculptures, Dr. A. V. Kidder deemed the stone carvings of sufficient importance to merit sending the staff artist of the Carnegie Institution's Guatemala Office to the site to make detailed drawings of them. We were glad to accept this cooperation and the services of Sr. Antonio Tejeda.

Owing to unavoidable circumstances, the drawings did not arrive in time for inclusion in the monograph, and we therefore stated that they would appear in *El Palacio*. It was found, however, that the reduction necessary for that format would cause too much loss of detail. Consequently, they are being issued in this form so that they may reach students of Middle American archaeology without further delay. A full discussion of the drawings is given on pages 33–45 of the original report, to which readers are referred.

Otomi Looms and Quechquemitls from San Pablito, State of Puebla, and from Santa Ana Hueytlalpan, State of Hidalgo, Mexico

Bodil Christensen

The looms to be described below are used for weaving a capelike garment worn by Indian women in several parts of Mexico and called a *quechquemitl*, from the Nahuatl *quechtli*, "neck," and *tlaquemitl*, "garment." The Otomi word for the same garment is *monhuí*.

The *quechquemitl* is a pre-Cortesian garment. In codices and documents written shortly after the Spanish conquest we find illustrations of goddesses and noble women wearing *quechquemitls*, whereas women of the lower classes are pictured wearing *huipiles*. We also find representations of *quechquemitls* on pre-Cortesian stone sculptures and on clay figurines.

The *quechquemitl* is usually made of two rectangular pieces of cloth sewn together by joining the end piece of one (a) to the long side of the other (b), and vice versa, thus forming a garment with an opening in the middle for introducing the head (Figs. 78.1.1–78.1.3). This *quechquemitl* is worn either with the points hanging toward the front and back (Fig. 78.1.2) or transversally with the points hanging over the shoulders (Fig. 78.1.3). It is in use amongst the Otomies, Aztecs, Totonacs, and Tepehuas.

The Huastecs, the Huicholes, and the Coras make their *quechquemitls* of two square pieces joined together at c and d (Fig. 78.1.4), leaving an opening for the head; or of one long piece folded over at e and the selvages joined at f almost to the top. To make the opening for the head, part of the fold at e must be cut (Fig. 78.1.5). These *quechquemitls* are made of commercial cotton materials; those first described

are made of handwoven fabric. A very unusual type is shown in Figures 78.1.6, 78.1.7, and 78.1.8. When worn, it resembles the rectangular type in Figures 78.1.2 and 78.1.3. It comes from the State of Puebla, but the exact place is unknown.

The peculiarity of the Otomi loom lies in the fact that it produces the two pieces of the *quechquemitl* not exactly rectangular but woven into shape, forming a graceful curve which falls over the shoulders. The two looms I obtained in San Pablito are slightly different, and a third one from the Otomi village of Santa Ana Hueytlalpan, near Tularicingo, Hidalgo, is quite different; but all produce a curved fabric by using part of the warp as weft.

Loom 1, San Pablito (Fig. 78.4.12): This is a double-length loom, having been warped for both parts of the *quechquemitl* at the same time. The loom is 2 m long from bar to bar inclusive. All sticks in the loom, with the exception of the end bars and the sword, are bamboo, the shed roll having a diameter of 2 cm and the rest about 1 cm each. Bamboo sticks are preferred because of their smoothness, light weight, and straight lines; but a stronger wood is necessary for end bars and sword. Spanish-speaking Indian women usually call a stick loom *otates*, using the Spanish adaptation of the Nahuatl word *otlatl* (bamboo), instead of the Spanish word *telar* (loom), which is applied only to a foot loom.

The end bars are of hard wood, 2.5 cm in diameter and 66 cm long. The warp is continuous and is attached to a heading cord of maguey fiber, the extension of which is used as binding string

for fastening the warp to the end bars. These are shaped at the ends to keep the ropes and heading cord from sliding.

The warp consists of three different sections with the following dimensions (Fig. 78.3.9):

- Section a: 22 cm of white 2-ply cotton yarns (12 to the centimeter).
- Section b: 19 cm of red wool yarns (8 to the centimeter).
- Section c: 5 cm white cotton border, similar to that described under a.

These measurements are taken from the finished fabric, which is 46 cm wide. The warps must be more than twice the length of each part of the quechquemitl, plus almost double its width, which will be understood from the description below.

The woolen yarn employed is hand spun, but not by the weaver herself. She buys it from an Indian from Texcoco, Mexico, who makes a trip to Pahuatlan and surrounding villages every twenty days, selling his wares. The white cotton yarn is a commercial product, which is sometimes respun by the weaver to make it the desired coarseness. It is bought from the merchants in Pahuatlan, Puebla.

The weft is white cotton yarn, wound on the bobbin in pairs of singles. The bobbin is a slender stick and the weft is wound around it in long spirals, so as to make an even thickness throughout its length. The tenter is placed underneath the weaving to which it is fastened by means of two thin thorns, or twigs from an orange tree. The heddle consists of two sticks; the loops (a thin cotton string) are continuous, put on in a spiral forming a figure 8, the crossing lying between the sticks. It is followed by a shed roll and a lease stick. More or less midway between the two end bars, the red warp yarns are twisted around a stick in bunches of eight, probably to add more length to this part of the warp in comparison to the cotton warp. The sword is of hard wood, 77 cm long and 5 cm wide, tapered at the ends and from the back toward the front. As the weaving progresses, the finished fabric is rolled up on the lower end bar and a supplementary cloth bar of similar type, which is placed on top of the end bar. The backstrap, 93 by 8 cm, is a matting plaited of palm leaves, with a small string at each end with which it is fastened to the lower end bar and reaches around the weaver's hips. It is similar to the tumplines used in this part of the country. The weaver sits on the ground with her legs stretched out in front of her or pulled up under her. The loom is tied to a tree in a slanting position, with a rope which is attached to the upper end bar, forming an inverted Y with an

78.1. Different forms of quechquemitls (nos. 1–8).

adjustable loop where it divides, so as to secure an even balance (Fig. 78.2.10).

The weaving starts at the heading cord. There are 10 picks to the centimeter in the cotton web; but on account of the difference in coarseness between the cotton warp and the woolen warp, 3 picks in one shed alternate with 1 pick per shed in the woolen part of the web. This is produced by changing the shed three times on every fourth pick; it gives a warpface to the web in Section b, while the cotton web is plain weave all through the fabric.

When 58 cm of cloth have been woven (Fig. 78.2.9, G–H), the shaping of the round shoulder begins. (To follow this part of the weaving on Figure 78.2.9, the illustration must be turned around, with A as the upper end bar.) Starting from the right side (where the narrow white-border is situated at this stage of the weaving), the pick does not go all the way through to the opposite selvage, but turns back in a countershed at the end of the woolen warp at I; the third pick lies in a new shed in the narrow cotton warp, but in the woolen warp it lies in the same shed as Pick 2; catching around the last red warp yarn, it

78.2. Loom 1, San Pablito (no. 9): (a) lower end bar; (b) upper end bar; (c) heddle; (d) shed roll; (e) lease stick; (f) supplementary stick (see also Fig. 78.4, no. 12, no. 10); rope with adjustable loop, used for tying loom to tree or other support.

turns back, still in the same shed in the red warp, but in a countershed in the narrow cotton warp. Pick 5 lies in a shed by itself both in the cotton and in the woolen warps, but it turns back eight warp yarns before the first four picks; it is followed by Picks 6, 7, and 8 in a similar manner as described for 2, 3, and 4. Each group of four weft yarns reaches the same point, but each group is eight warp yarns farther away from the middle of the fabric than the preceding group, forming a receding line until the opposite side of the woolen warp is reached (Fig. 78.2.9, I-J). Then the weaving is stopped, and the loom is turned so that the lower end bar B now serves as upper end bar. The heddle and shed roll are removed and placed on this half of the loom in their proper positions, and the weaving of the second rectangular piece proceeds exactly as described above.

When the receding part of this half is finished (Fig. 78.2.9, I'-J'), the interesting part of the weaving begins. The shed roll is removed from the woolen warp and placed in a new shed in the white cotton warp (Section a). This shed is formed by groups of six pairs of warp threads in the following manner: after the crossing in front of the lease stick, the warps are given an extra twist, but this time in groups of from six to eight threads (the grouping is not very exact), so that the warps which passed over

11

78.3. Looms from San Ana Malacatan (no. 11): (a) lower end bar; (b) upper end bar; (c) heading strip; (d) heddle; (e) shed roll.

the lease stick and which consequently should pass under the shed roll, also pass over this, six over and six under, etc. Part of the woolen warp is cut on the weaver's side of the middle rod, to which this part of the warp is twisted in bunches of eight yarns, as

mentioned before. The strands of loose warp, starting with the one nearest to the broad cotton warp (Section a), are now passed with the fingers through the shed of the cotton warp from I' to Q', thus being used as weft, floating over six and under six warps,

12

13

78.4. Looms from San Pablito (nos. 12 and 13).

corresponding to the special spacing of the warps on the shed roll. The weft is pushed together with an instrument made of a heavy wire pointed at one end, and is afterwards beaten into position with the sword. This gives a weft-face to the transversal band of red, as the wefts are pressed together so closely as completely to conceal the warps. At the opposite sel-vage, the weft is turned back in the countershed for a couple of centimeters and left hanging, to be cut off close to the web when the weaving is finished.

This is the stage at which I procured Loom 1 in San Pablito (Fig. 78.4.12).

Sometimes the warp setup has been miscalculated, so that when cut, the red warp yarns are not long enough to reach to the opposite side and turn back; then an extra strand of yarn is added, but the weaving loses in quality by this procedure.

All the woolen warps, which were cut not all at the same time but part by part to avoid getting them entangled, are passed through the cotton warp

as weft, one by one, bringing the receding part of the woolen web I'-J' up against the cotton warp at I'-K', and giving the impression of the red border turning a corner. This causes a certain pull on the cotton warp, making the weave looser, especially in the part closest to the joining. This can be noticed by the difference in width of the red transversal band, which at the beginning had the same width as the cotton web, but at the end is about 5 cm broader from sel-vage to the receding line. The loops from the heddle stick, which have been disengaged by cutting the woolen warps, are cut and unwound, and the string is tied together again.

When the last loose strand has been used, the weaving continues with the white cotton weft on the bobbin, thus forming a border 5 cm wide in plain weave, corresponding to the narrow border at the side of the web (Section c). It will be noticed that now the cloth is narrower than when the weaving was started, as the part of the warp formed by the

14

16

15

17

78.5. Loom from San Pablito (nos. 14–17).

red wool yarns (Section b) has been eliminated (Fig. 78.4.13).

Finally the position of the loom is reversed a second time, so as to finish the shaped part of the first rectangular piece. The shed roll is placed on the other side of the lease stick; and the heddle, which now passes through only the cotton warps, is placed between the weaver and the shed roll.

The woolen warps, which have been taken off the middle rod, are hanging loose and will be used as weft, forming the transversal border on the second part of the quechquemitl.

There is no special finish to the weaving, but the warps are cut off close to the web and a narrow hem is made, each part of the quechquemitl being a three-selva fabric, 4.6 cm wide by 82 cm long.

When the two pieces are sewn together, as described in the beginning of this *Note*, the curves formed by turning the warp into weft fall exactly

over the shoulders of the wearer, giving a graceful line to the quechquemitl.

Loom 2, San Pablito (Fig. 78.4.13): The dimensions of this loom differ slightly from the one described above, but, like the former, it is a double-length loom. The heddle consists of one stick, and the loops are put on in spiral form. The weaving on this loom is at a more advanced stage than on Loom 1, as one part of the quechquemitl is finished and the loom has been reversed a second time. The bobbin is inserted in the shed between the shed roll and the finished part, taking the place of the lease stick. The woolen warps are hanging loose; ready to be used as wefts for the weaving of the transversal band. The loops which encircled the woolen warps have been cut off and the string tied together again.

Loom 3, San Pablito (Fig. 78.5.14): This is a single-length loom. As will be noticed, the transversal band is being almost finished, as only a few strands of

loose warp yarns are left to be introduced as weft, and then a narrow white border, using the long bobbin, will finish this half of the quechquemitl. The warp will have to be cut, as the loom has no heading strip. The heddle is made of two sticks, as on Loom 1. A very heavy shed roll and a lease stick are in place, and an extra stick, which does not appear on the other two looms, is attached to the cotton warp of the narrow white border to the left of the loom.

The quechquemitls from San Pablito may be divided into two main groups: (1) those with a broad woolen band, 15–24 cm wide (Figs. 78.7.22, 78.7.24, 78.7.26), and (2) those with a narrow woolen band, 7–8 cm wide (Figs. 78.7.23, 78.7.25, 78.7.27).

The wide border is always a brilliant red; the narrow borders are purple. The red borders are divided in the middle by a black and orange line 1 cm wide, or an all-black line. The purple border has an orange line of 3 or 4 warp yarns through the center.

The white upper part of the quechquemitl is decorated with embroidery in cross-stitch, the main colors being black and red; occasionally an orange or magenta touch is found. The woolen border is never decorated with embroidery. The embroidery yarn is wool which has been split into 2-ply strands, or commercial embroidery cotton. Two kinds of cross-stitch are used: the simple one, and one where the stitch to the right is twice as long as the backstitch, giving a braided effect to the row. Each stitch is completed before a new one is started. A few motives are surrounded by an outline stitch in red.

The motives may be divided into three styles:

1. A narrow decorative border along the joining seams, and in the corners and in front and back adjacent to the woolen band, the pattern being a row of highly stylized little men (Figs. 78.7.22, 78.7.23).
2. The same borders as above, but the whole upper part decorated with zoomorphic motives: double-headed eagles, deer, birds, rampant horses, jaguars, turkeys, monkeys, foxes, rabbits, in fact every animal from the region, represented with a high degree of stylization and a rich imagination. We also find an occasional human figure, male or female (Figs. 78.6.21, 78.7.24, 78.25).
3. Same borders as in (1) and in addition four big motives, one in each corner and one in front and back, in conventionalized designs of pots with flowers resembling stars and rosettes. Suggestions of the aboriginal signs *illhuil* and *xicalcolihqui* are found as negative designs inside the motives (Figs. 78.7.26, 78.7.27).

The three styles of decorative motives are found in both the quechquemitls with the broad red band

and those with the narrow purple band, making a total of six different styles (Figs. 78.7.22–78.7.27).

Unfortunately, commercial cotton material (unbleached muslin) is taking the place of the handwoven cotton material, but a handwoven woolen border 7 cm wide is inserted 5 cm from the edge. This strip is not woven with a corner, but cut and sewn together by hand, forming the corner. The color is dark blue-violet with an orange line in the middle. The quechquemitl may be left without embroidery, or Styles 1 and 3 may be employed. I have not yet found a quechquemitl made of commercial cotton decorated with Style 2.

Loom 4, Santa Ana Hueytlalpan (Figs. 78.3.11, 78.5.15–17): In Santa Ana all looms are of the single-length type with a double start, which is more economical, as no part of the warp is wasted and it has the advantage of producing a four-selvage fabric.

The loom in Figure 78.5.15 is 60 cm long from bar to bar inclusive. The dimensions of the different sections of the warp setup are as follows (Fig. 78.3.11)

- Section a: 23 cm of white 3-ply cotton yarns, very hard spun (16 to the centimeter).
- Section b: 16.5 cm of red woolen yarns (10 to the centimeter).
- Section c: 8 white cotton yarns, which form the selvage at the opposite side.

Section c is part of Section b, which has been divided at the upper end bar, giving space for Section b, which is not attached to the lower end bar.

Through Section b run five lines of green warp yarns as a decorative motif: two close to the margins and one in the middle.

The cotton yarn used for the warp in Section a and for the weft is commercial cotton, which is sometimes respun by the weaver to make the desired coarseness. The raw wool is bought for \$15.00 pesos a kilo; it is carded, spun, and dyed by the women themselves. Aniline dyes are used, which at the present time cost \$6.00 pesos a kilo.

The cotton warp and the woolen warp are warped apart, the woolen warp being as much longer than the cotton as the width of the loom and a bit more. The yarn is dyed after it is warped. Then both the cotton warp and the woolen warp are dipped in a sizing of corn gruel, placed on end bars, and dried in the sun. When the two warps are dried apart, the woolen warp is not cut until setting up the loom; but if they are dried on the same end bars, the woolen warp is cut at one end and tied in four bunches at the upper end bar. When the warp is dry, a heading cord of maguey fiber is introduced in the sheds at

18

19

20

21

78.6. Different forms of quechquemitls (nos. 18–21).

either end instead of the bars, the surplus being used as binding string for fastening the warp to the end bars. At this point the eight cotton warp yarns have been separated from the rest at the end bar B, giving space for the woolen warp yarns. The white cotton warp is continuous, whereas the woolen warp has been cut.

The end bars, of hard wood, are about 53 cm long and 3 cm in diameter. The heddle is a stick 67 cm long and 1.5 cm in diameter. The loops are continuous and are put on the heddle in alternate form; the string is the same hard spun cotton yarn as warps in Section a. The shed roll is a bamboo stick 83 cm long and 3 cm in diameter. The sword is of hard wood, 74 by 4 cm, tapered at the ends and from the back towards the front. The backstrap is a leather band, 80 cm long and 2.5 cm wide, fastened to the lower end bar with loops made of maguey string. A

lease stick is used only while weaving the transversal band, not for the plain weave. This loom has no tenter, probably because the warps are very coarse and short; but usually a tenter is put on after the corner is finished and the plain weave begins. The weft is a pair of 2-ply loosely spun cotton yarns and the bobbin is the primitive longitudinal type.

The weaving starts with a heading strip of about 2 cm. While this is being woven, the woolen warps are tied to the upper bar, using A as upper end bar. Then the loom is turned so that B becomes the upper end bar, and the weaving of the curved shoulder is started.

The shed roll is pushed back to take the function of a lease stick, and a new shed roll is inserted between the lease stick and the heddle in a shed being formed by groups of six cotton warps, which are twisted around themselves, as described under

78.7. Different forms of quechquemitls (nos. 22–27).

Loom 1. (Or the long bobbin may be used as lease stick, as in Fig. 78.5.16, inserting it in the white warp while the transversal band is being woven.) The long 'woolen warps are untied from the end bar A and starting with the one farthest to the right, each strand is passed through the cotton shed as weft, floating over six and under six warps. At the opposite side each weft is turned back in a countershed for a couple of centimeters so as to form a selvage. The ends are left hanging, to be cut off close to the web when the fabric is finished.

When all the woolen yarns have been used as weft, the triangular piece between d, e, and f is woven, using the cotton weft and a small, thin stick as bobbin, 38 cm long and 0.5 cm in diameter, making frequent use of fill-in wefts to make the line e-f-g as straight as possible (Figs. 78.3.11, 78.5.16). When the corner is woven, the extra shed roll is removed, eliminating the special shed formed by grouping and twisting of the cotton warp yarns. The rest of the weaving is completed with the cotton weft on the long bobbin in a plain weave from selvage to sel-

vage. To compensate for the difference in coarseness between the two warps, two methods are used: one as described under Loom 1 by occasionally passing three wefts through one shed in the woolen warp, and the other by fill-in wefts in the cotton warp, turning back the weft in a countershed before passing it through the woolen warp (Fig. 78.5.17). No special rule seems to be followed, but each weaver uses her own judgment in evening up the web. All through the weaving frequent use is made of the wooden comb with which the weft is pushed together very tightly by swift, hard, scratching movements. The maguëy thorn is principally used for separating entangled warp yarns. The weave is very tight and the finished fabric is stiff and coarse, whereas the San Pablito quechquemitl is woven loosely and falls softly.

When nearing the heading strip, the shed becomes so narrow that the sword cannot be used. Thinner and thinner sticks are used as shed rolls, and when at last not even the thinnest shed roll can be used, the picks are put through by means of a

78.8. Different forms of quechquemits (nos. 28–33).

long, coarse needle (length about 25 cm). To close up the very last space, the weft yarns on both sides of the open space are pushed together with the comb, so that the joining becomes as invisible as possible. The advantage of a double start is that the web becomes a four-selvage fabric and there is no need of cutting the warp and hemming the end.

The Santa Ana quechquemitl (Fig. 78.6.18) is small in comparison to the one from San Pablito (Fig. 78.6.19), each part measuring only 55 by 40 cm. Others in my collection measure 50 by 34 cm and 46 by 31 cm. The two pieces are sometimes joined together with a peculiar darning stitch from 10 to 15 cm wide made on the bias by the long needle described above; double strands of red wool yarn with a zigzag line run from top to bottom, part of the line being in blue and part in green (Fig. 78.6.20).

The weaving of the quechquemitl takes two days for a good weaver, besides the time spent in preparing the wool and setting up the loom. The embroidery joining the two parts takes one day. The Santa Ana quechquemitl never has embroidery on the white upper part as does the San Pablito quechquemitl. The width of the red and white parts

of the quechquemitl varies, as Indian fabrics are never standardized but highly individual. The weavings are made for personal use, or as orders for women who do not themselves know how to weave.

Occasionally the Santa Ana quechquemitl is woven of all wool warps. Then the grouping and twisting of the white warp forming the special shed for the transversal band is not necessary, as there is no difference between the white warp and the red woolen strands used as weft. For weaving the corner and the plain weave a cotton weft is used.

Examining quechquemits from other parts of the Sierra of Puebla, Hidalgo, and Veracruz, we find that sometimes a narrow border of contrasting color, woven in the "round shoulder technique," has been used as adornment. I may mention Cuetzalan, Puebla [Nahoas] (Fig. 78.8.28); Mecapalapa, Puebla. [Totonacs] (Fig. 78.8.29) in which half a quechquemitl is shown; Tenango de Doria, Hidalgo (Otomi), and Atla (Fig. 78.8.30), Xolotla (Fig. 78.8.31) and other Nahuatl-speaking villages in the State of Puebla between Pahuatlan and Huauchinango. In Zontecomatlan, Veracruz (Nahoas), we find a quechquemitl woven with the Santa Ana technique, but of an in-

ferior workmanship (Fig. 78.8.32). The white upper part is, decorated with heavy wool embroidery, entirely concealing the white fabric. The colors are red and orange with blue, green, and magenta spots. The embroidery is made of cross-stitch, forming loops about 1 cm long on the front, which gives a resemblance to a hooked rug. The patterns of birds, animals, flowers, and other designs are distinguishable only on the reverse side of the embroidery (Fig. 78.8.33). The two parts of the quechquemitl are joined together by a netlike stitch 5 cm broad of wool

yarn, alternating 4 cm in red and 4 cm in green. This quechquemitl is small and stiff, measuring 52 by 28 cm.

This paper does not pretend to have completely covered all phases of the weaving of the San Pablito and Santa Ana quechquemits. Only by watching different weavers from start to finish would it be possible to observe each little detail; but I hope I have explained the main differences between the weaving of these quechquemits and that of other better-known garments.

MEXICO, D.F.

Maya Calendar Round Dates Such as 9 Ahau 17 Mol

Tatiana Proskouriakoff and J. Eric S. Thompson

It has been known for very many years that the positions in the months held by each day were one less in Yucatan at the time of the Spanish conquest than they had been in the cities of the Central area during the Classic or Initial Series Period. That is to say, combinations such as 12 Kan 1 Pop, 6 Imix 3 Yax, or 13 Ahau 17 Mol were used at that time in Yucatan, whereas in the Central area during the Classic Period those dates would normally have been written 12 Kan 2 Pop, 6 Imix 4 Tax, and 13 Ahau 18 Mol.

It has been generally supposed that the backward shift of one place in month positions was a late innovation, not long antedating the Spanish conquest, and perhaps connected in some way with the Mexican domination of much of the Maya area. We believe that this shift occurred at a quite early date in Campeche and, perhaps, elsewhere, and that it is characteristic of the Puuc area.

Across the top of the front of Stela 9, Etzna, there are seven glyphs. The first two record quite clearly 9 Ahau 17 Mol. The next sign is the head of an animal, perhaps with the Chicchan ornament on its forehead, and, therefore, conceivably with the numerical value of 9 or 19. Glyph 4 is a katun sign. There follows next a hand with a bracket prefix. The best interpretation of this part of the text can be made by assuming that the head represents the number 19. The whole would then read: (9.19.0.0.0) 9 Ahau 17 Mol, 19 (?) katuns completed. Whether that reading be acceptable, or not, there can be no doubt that the two opening glyphs record 9 Ahau 17 Mol, whereas one would normally expect 9 Ahau 18 Mol. The junior

author recently inspected this stela in the regional museum in Campeche, and convinced himself that there never had been a third dot (Fig. 79.1d).

Stela 18, Etzna, records an Initial Series of 9.12.0.0.0 10 Ahau. There follows the Lunar Series, recording a moon age of 25 days, 5 moons. C1 is Glyph B of the Lunar Series; D1 should be Glyph A, but is not identifiable as such. C2 has a coefficient of 7. The glyph itself consists of a weathered element with a recognizable kin tail beneath, and a superfix which has the outline of that of Yax. The inner circle is recognizable. There can, we think, be little doubt that the whole represents 7 Yaxkin. This is the position where one would expect to find the month sign (the second glyph after Glyph B of the Lunar Series) in view of the fact that it is not placed after the day sign. Moreover, the tail and what can be seen of the superfix indicate, that the whole is the month sign Yaxkin. The whole, therefore reads: 9.12.0.0.0 10 Ahau 7 Yaxkin, whereas one would normally expect 9.12.0.0.0 10 Ahau 8 Yaxkin (Fig. 79.1b).

Stela 19, Etzna, has an Initial Series, the opening glyphs of which are absent. However, the surface of the top left corner of the stele is rough, and it is probable that a piece of the original surface, carrying the missing glyphs, has flaked off.

A1, B1, and A2 record 0 uinals, 0 kins, 8 Ahau. A3 is occupied by Glyph G9 and what is probably Glyph F. There follows a record of a moon age of 21 days, 6 moons.

Glyph B2, which follows 10 Ahau, has a coefficient of 7. The junior author studied the rather worn

79.1. Calendar-round dates with month positions one day less than normal: (a) 7 Muluc 1 Kankin (?); Holactun, Temple of the Initial Series; (b) 10 Ahau 7 Yaxkin (?); Etzna, Stela 18; (c) 8 Ahau 7 Uo (?); Etzna, Stela 19; (d) 9 Ahau 17 Mol; Etzna, Stela 9; (e) 6 Ix 16 Kankin; Yaxchilan, Stela 20; (f) 3 Eb 14 Mol; Yaxchilan, Stela 18; (g) 2 Chuen 3 Muan; Kabah, Structure 1, jamb.

glyph in the regional museum of Campeche, and believed that he could see the details as reproduced in Figure 79.1c.

Possible restorations of the defective Initial Series, together with the approximate moon age at the dates in question, are:

A	9.13.0.0.0	8 Ahau 8 (or 7) Uo	Moon age approx. 22 d.
B	9.16.5.0.0	8 Ahau 8 (or 7) Zotz	Moon age approx. 5 d.
C	9.19.10.0.0	8 Ahau 8 (or 7) Xul	Moon age approx. 15 d.

As a moon age of 21 days is recorded on this stela, Readings B and C can be eliminated, leaving only one date which is in close agreement with the lunar data.

Glyph B2, accordingly, should represent 7 Uo. Hitherto, no head variant of Uo has been reported, and we have, there fore, no examples with which to compare it. The characteristics of Uo are the crossed bands and the superfix with crosshatching, to represent black. Crossed bands are not visible on the somewhat worn head at B2, but there is an area with crosshatching behind the eye. All in all, it is at least probable that the glyph is a head variant of Uo. The Initial Series, accordingly, can be accepted with little doubt as recording 9.13.0.0.0 8 Ahau 7 Uo. The read-

ing of the Initial Series as 9.13.0.0.0 (as also that of Stele 18 as 9.12.0.0.0) was first made by Alberto Ruz L. (1945a:59).

No other Calendar Round dates at Etzna are sufficiently well-preserved to indicate whether their month signs were in what we might, perhaps, term Puuc style, or the usual method. However, in all three inscriptions in which the month glyphs can be determined with fair to complete certainty, their attached coefficient is one less than one would expect.

On an ornamented shell, as yet unpublished, which is supposed to have been found at Jaina there is an inscription, the opening glyphs of which read 3 Caban, kin, 14 Muan. The style of the beautifully cut glyphs is that of the Central area during the Classic Period; the interposition of the kin sign between day and month is characteristic of Chichen Itza and northwestern Campeche. It is, therefore, highly probable that this shell was carved in an area, most logically central Campeche, in which these regional differences meet. The best position for the date is 9.13.14.16.17 3 Caban 14 Muan, plus or minus one Calendar Round. It will be noted that by normal standards one would expect the month position 15 Muan.

The Initial Series at Holactun (Xcalumkin), in northwestern Campeche, has been read by both Beyer and the junior author as 9.15.12.6.9 7 Muluc (2 Kankin). There is no month glyph between the day sign and the Lunar Series. It should, therefore, be sought after Glyph A of the Lunar Series. There is, in fact, a glyph at that position, although it is of unfamiliar form. The coefficient is 1. Since, so far as is known, the month position of an Initial Series is never omitted, we can be reasonably sure that this is the month symbol. It may be an unfamiliar form of Kankin, just as an unfamiliar form of Uo apparently occurs on Stela 19, Etzna (Fig. 79.1a). This is a region which differed from the Central area, not only in architecture and ceramics, but also in many hieroglyphic forms (note the many unusual glyphs at Holactun). It is not surprising, therefore, to find unusual variants of familiar signs.

The north jamb of the doorway of Structure 1, Kabah, carries a date 2 Chuen, kin, 3 Muan, instead of the 4 Muan one would expect to find. This is the only Calendar Round date now known at Kabah. We can, therefore, feel reasonably certain that the shift in month positions was also followed at this important Puuc site (Fig. 79.1g).

At Uxmal there are a few Calendar Round dates which appear to show the same backward shift in month positions. The ring of the east wall of the ball court carries a date ? Ix 16 Pop, falling in tun 17 of (a katun) 12 Ahau. This may be the equivalent of

9.10.16.6.14 9 Ix 16 Pop. In any case Ix is linked with 16 Pop in contrast to 17 Pop of normal usage. On the ring of the west wall there is a day sign which, as drawn by Morley (1920:514), looks like an inverted Ix. There is a partly destroyed head coefficient, the best reading of which Morley considers to be 10. This is followed by 17 Pop, a glyph usually found in these texts before the winged Cauac, and a coefficient which is 12 or 17. A detached fragment has a winged Cauac and 12 Ahau. Morley reads the day sign as Ix, and supposes that the double text gives the same date in both systems. Against that interpretation must be set the fact that the day sign apparently is not Ix. Unfortunately, it is in poor condition, having weathered badly. The junior author (Thompson 1937a:194) came to the conclusion that the glyph was a head variant. That the date is 10 Men 17 Pop, the day following 9 Ix 16 Pop, is a possibility. In any case the combination Ix 16 Pop indicates that the backward shift was observed at Uxmal. It is now known from ceramic evidence that Uxmal was abandoned at a relatively early date, almost certainly before 10.10.0.0.0. The shift, therefore, is not attributable to the period immediately before the Spanish conquest.

Morley (1920, Fig. 74) and Blom (1934) reproduce drawings of a text on a capstone in the east wing of the Monjas, Uxmal. This opens with a Calendar Round date 5 Imix 18 (or 19) Kankin. Morley believes the coefficient to be 18; Blom shows it as 17. The complete date has been deciphered as (10.3.17.12.1) 5 Imix 18 Kankin, falling in tun 18 of katun 12 Ahau (Thompson 1941a:107). It is probable, although not completely certain, that this text shows a shift backward in month coefficients.

There is a second capstone with a hieroglyphic text in the Monjas at Uxmal which has been illustrated by Blom in the cited work. This apparently reads 4 Eb 15 (or 5) Ceh, the coefficient of the month being a head variant. This date would therefore indicate that both systems of transcribing dates had been used at Uxmal at one time or another.

The same may have been true of Holactun. In the same building which contains the Initial Series there is a day 2 Ix followed by an unidentifiable glyph with a coefficient of 2. If this is a month sign, it conforms to the regular method of month recording.

Two instances of the backyard shift in month positions occur also at Yaxchilan. On Stela 18, at A2, A3, is a date read by Morley as 3 Cimi 14 Mol. The Maler photograph, however, shows clearly a line flanked by a row of dots curving from the upper right margin of the glyph, which identifies the day sign as Eb and not Cimi. Clearly 3 Eb 14 Mol is the date recorded, though 15 is the expected month

coefficient (Fig. 79.1f). A similar case occurs on Stela 20, on which the day 6 Ix (A1, b), is followed by an animal head, which Morley suggests represents the month Mac. It is, however, in all probability Kankin. In any case the coefficient is clearly 16 (A2). Neither of these monuments records an Initial Series, and both are carved in a style which is peculiar to a group, of sculptures at Yaxchilan and which has closer affinity to some styles in the Puuc region than to the classic styles of the Peten. The pointed shape of Stela 20, very rarely encountered in the Peten, is similar to that of Stela 3, 5, 6, and 8 of Sayil and Stela 3 and 4 of Santa Rosa Xtampak. The treatment of the legs of the figure and of the apron of the *ex* (loincloth) is also characteristic of these sculptures. The figure wears no skirt, and the rounded outline of the thighs is strongly accented. The inner outline of the leg to above the knee is left free either by deliberately deflecting the apron of the *ex* or other low-hanging elements, as on Stela 20 at Yaxchilan and Stela 5 and 6 at Sayil, or by designing the end of the *ex* to parallel the line of the legs, as on Stela 3 at Xtampak. The short sleeveless jacket worn by both Yaxchilan figures is another feature that is not represented in Peten sculpture but occurs in Yucatan on the carved jambs of the building known as the Codz Poop at Kabah. In view of the fact that the two regions share a number of traits to the exclusion of the Peten, it is not particularly surprising to find the Puuc style of date notation used also at Yaxchilan.

Unfortunately, the two monuments bearing this notation are not dated by their inscriptions and there are no close stylistic analogues by which a certain determination of their stylistic period can be made. There are some indications that Stela 18 and 20 are not earlier than 9.15.0.0.0, as, for example, the design of the bag on Stela 18, with its ornament of rattles ending in a scroll, a type which at Piedras Negras occurs for the first time in 9.15.0.0.0 and is characteristic of later monuments, and the very high wristlets worn by the figure of Stela 20, that re-

semble those on Stela 5 and 7 at Seibal and the two figures at El Caribe, all of the period after 9.15.0.0.0. On the other hand, there are no specific traits of the two Yaxchilan sculptures which would suggest that they were carved in the tenth cycle, or that they are much later than other monuments at this site. The best chronological position that can be assigned to the style is therefore somewhere between 9.15.0.0.0 and 10.0.0.0.0.

Both these Yaxchilan texts are very unusual in another respect. In both cases the day sign is preceded by a kin glyph. As is well known, at some sites in Yucatan and Campeche (notably Chichen Itza, Holactun, and Kabah) a kin sign often follows the day sign, being placed between day and month signs. It is not impossible that the insertion of these kin signs at Yaxchilan before the day signs is merely a variant of the custom of placing the kin sign after the day sign. With the exception of these two stela at Yaxchilan, kin signs do not accompany day signs on any texts of the Central area, to the best of our knowledge.

Another example of the backward shift in month position is supplied by a lintel recently discovered by Mr. Giles G. Healey at Bonampak, in the Lacanha drainage, Chiapas. This carries the Calendar Round date 1 Ix 1 Yax (conceivably 1 Ceh), whereas one would normally expect 1 Ix 2 Yax. The art and architecture of this site resemble rather closely that of Yaxchilan. Indeed, the two ruins are not far distant as the crow flies, although as the Maya walks, the journey is more formidable.

The evidence, then, would appear to indicate that in the Puuc region the custom of recording month positions as one less than normal became established at least as early as 9.12.0.0.0, although it is not at all certain that the new system entirely replaced the other at any time. There is also evidence that in the Middle Usumacinta, where art styles indicate contacts with northern Campeche, the shift backward in month positions at one time obtained, although this heterodoxy may have been of short duration.

Stone Objects from Cocula and Chilacachapa, Guerrero

R. H. Barlow

At the Fourth Mesa Redonda, Sr. Covarrubias presented a typology of the stone figures which abound in the region of Mezcala and other parts of Guerrero. When available in a formally published version, this typology will help to anchor the lithic work of Guerrero, which appears frequently in private and public collections but lacks exact information. As distribution in space demands attention, certain pieces found by Ing. Weitlaner and myself are herewith put on record.

Cocula, which was Matlatzinca-speaking in contrast to its Chontal neighbors (Toussaint 1931), provides one "idol", the word may not describe the real function of such sculpture, and two anomalous objects. The "idol" (Fig. 80.1.1) is carved on pale green stone of a poor quality and is notable for its attire: a sort of top-hat and a on. (The historic Tarascans also wore shirts instead of loincloths.) This figure, from El Rincon, near Mina Vieja, close by Cocula, belongs to Sr. Camerino Sanchez.

Well inside the town of Cocula, a carved lintel (?) was dug up in a barnyard (Fig. 80.2.4). Made of *piedra azul* (actually, nearer slate gray), it is carved on four sides with a continuous groove

which passes from one face to another. On the wide edge appear an eye and a brow; on the thin one, an arrowhead and a shaft. (The Matlatzinca of Cocula used the sling [Relacion de Iguala].) The same line which divides the eyebrow from the eye forms, on another surface, the arrowhead. Both ends of the piece are broken off. It belongs to Sr. Hernando Meneses.

Another geometrically incised object in Cocula was drawn by Ing. Weitlaner (Fig. 80.3.5). This is a stone "stirrup" with ornamentation on both ends which seems to repeat the eye motif. Certain areas of the surface were left rough for decorative purposes, and the rest was polished.

Chilacachapa, six hours on horse above the Valley of Cocula and in the heart of the old Chontal-speaking district, afforded two figures. One is green stone of a poor quality, and seems to wear a jupon like the Cocula figurine. Sr. Florencia Roman Segura generously obtained the loan of it for my drawing (Fig. 80.1.2). The other is a head of good-quality jade and sports a peaked hat. The football-helmet effect which covers the ears is either part of the hat or a Dutch-style haircut (Fig. 80.1.3).

Easter Ceremonies at San Antonio Palopo, Guatemala

Elsie McDougall

The small village of San Antonio Palopo is situated on the northeast shore of Lake Atitlan, a mile or two east of Santa Catarina Palopo. The villagers, Cakchiquel Maya, have no canoes; except for fish weirs, of stone or sod, their interests are in the land. Their principal industry is agriculture; their main crops are maize and anise. They cultivate every possible patch or pocket of soil on the steep slopes, at the base of which their village nestles. At the time of my visit (1929) there was only one non-Indian in the village. He was Ernesto Cabrera, who filled the sundry duties of secretario, public scribe, and schoolmaster, and owned the only beast of burden in the community.

The church dominates the village, and from it one has a magnificent view of the whole length of the lake. Various excellent photographs of the village and its inhabitants were published by Mr. and Mrs. Maudslay in their beautiful book *A Glimpse at Guatemala*. The only other building of importance is the *juzgado* (courthouse), which consists of one long room flanked by lock-up cells (Fig. 81.1).

On arriving at the village, I went to the *juzgado* to seek permission to attend the Easter celebrations. The *alguaciles*, who serve as village police and do any odd job required for the municipality, were lounging on the porch, holding their leather-thonged batons, insignia of their rank. Inside, the town councillors, about ten middle aged or old men, were seated on a bench which ran along the back wall. The *alcalde* (mayor) was at one end with his interpreter, Juan, beside him. All the men, as well as the *alguaciles*, wore typical *antoñero* dress consisting of a rusty-

black *gaban* (cloak worn as poncho, emergency sleeve lengths joined at the wrist and dangling toward the rear), which covered all but the red sleeves of shirts made of the same material as the woman's huipil; a black-and-white chequered woolen *rodillera* (wrapped kilt or apron) covering wide, knee-length cotton drawers of home-woven, striped cloth; and a red sash similar to the one used by women. Completing the dress was a fine-striped red kerchief (at times the man's sweat cloth or scarf) wound around the head, the two ends somewhat rakishly protruding. Permission was graciously granted to attend the celebrations, and I was assigned the padlocked schoolhouse as a residence.

About 8 a.m. on Holy Saturday I passed by the *juzgado*. The building was decorated with pine boughs, but the door of the main room was closed. The young *alguaciles*, before the wide-spaced wooden grills of the two cells, were keeping company with their incarcerated friends. These last were youths who had been arrested because of brawling and drunkenness in premature celebration of the fiesta. Traditionally, only the old men were supposed to get intoxicated on such occasions. The young men were expected to stay sober to look after their elders. The prisoners were happy, and were not to be deprived of their part in the festivities. In each cell one young man played a mouth organ, to the music of which his two or three fellow inmates managed to dance in a constricted circle. Evidently their crimes were not taken too seriously, for the prisoners were later released to attend the function in the church.

81.1. San Antonio Palopo: (a) Juan, the officiating priest, after the service; note palm, missal, and violin; (b) the courthouse and thatched shelter for the bells; the water in the fountain is piped from the mountain behind the village; the church is to the left.

The festivities centered around the two huts or lodges belonging to the two *cofradías* (religious brotherhoods). In line with each *cofradía* but was another in which the women prepared food. Each *cofradía*, too, had its own sweat house. The members of the principal *cofradía* had hired a marimba from Chicacao, which the four marimbistas played in the gloom at the back of the hut. The other *cofradía* had the town *teponaztle* (drum, *tun*) and an oboe-shaped flute (*chirimía*) the tone of which recalled that of bagpipes. The two musicians played just outside their *cofradía* hut, one on each side of the doorway.

The interiors of the *cofradía* huts were decorated. One was festooned with limes and oranges and greenery, and the floor was strewn with pine needles. The altar, profusely decorated with pine, stood to the left of the entrance, and on it were some battered saints, apparently salvaged from the façades or altars of derelict churches, and some old statues of San Antonio. The new one, of wood and a product of Panajachel, was gaily painted. It had the place of honor on the altar. Before it was a large gourd bowl of *chicha* in which seeds were floating; below it, on the floor, were censers. As each man entered and made obeisance to the emblems he was offered a small gourd bowlful of *chicha*. This he drank in one gulp, and then took his place among the dancers, circling the room in a trio of rapid steps, one forward, a short one back, and another forward. Each man danced with arms hanging down, his fingers clasping those of the dancer in front of him and behind him. In the second lodge the proceedings were similar except that a young woman, evidently intoxicated and with her baby in a sling on her back, had joined the dancers.

By 9.30 a.m. the courthouse door was open. The alcalde and Juan, the interpreter, were inspecting the Paschal candle and a three-branched candle, brought from Antigua by three young messengers.

The work of decorating the church was assigned to the court *alguaciles*, comprising the youth of the village. The main altar, filling the rear wall of the church, supported various saints in glass cases, San Antonio occupying the center. Some circular fans of fluted paper were a conspicuous part of the decoration. Below, on a ledge which ran across the width of the altar, had been placed the treasures brought from the sacristy: an illuminated missal, a tarnished lectern, and a small shield-shaped emblem of San Antonio. At the entrance other youths had placed water jars, adorned with boughs, on a table near the font. Young women and girls, arriving in groups, settled on the floor at the rear and on the right side of the church. Small boys, some with smaller brothers clad in borrowed shirts which enveloped them,

dogs, and a pet kid played around the youths who were decorating the church. Swallows, disturbed by the activity, flew under the roof.

The preparations finished, a youth ran to the bells (one dated 1730), which were in a thatched shelter before the church, and with a clapper in each hand, rang them briskly.

The members of the *cofradías* came in procession, headed by the chief with his staff of rank, and immediately behind the *teponaztle* and *chirimía*. The new "santo," taken from the staff, was placed on the ledge, adjoining the shield emblem of San Antonio. Each member of the *cofradías* made obeisance to it before taking his place in order, those of rank in front; the young men, *alguaciles*, and helpers to the rear, along the left side of the church. Four *chahalas* (women detailed for church duties), their heads covered with shawls of large squares of the lighter-patterned cloth, came last. They knelt in front, facing the altar.

Finally, Juan, as officiating priest, solemn and preoccupied, marched up the nave to the center of the altar. He had removed his head scarf, had donned spectacles, and carried under one arm a violin and a sheaf of torn leaves of music manuscript. Giving the violin to a sacristan, he opened the missal on its lectern in the center of the altar ledge, and began intoning in a sonorous voice which was a close-imitation of that of ordained priests. The language appeared to be Latin, although it was not possible to catch the words above the music of *teponaztle* and *chirimía*. At times he took the censer from the acolyte and censured the missal.

The shieldlike emblem of San Antonio, resting on the back of the acolyte's hand, was presented to each *cofrade* in turn and kissed by each one. Next, palm fronds brought from the sacristy were presented in formal sprays to the chief persons and then in torn strips to the women and children, who scrambled for them. Later, new wands, stoutly made and freshly peeled, were given to certain men, presumably the newly elected *regidores* (councillors).

At the intoning of the Gloria, Juan was handed his violin. This he apparently played while still intoning vigorously. Of that, however, I could not be certain because, facing the missal, he had his back to the congregation, and because the *teponaztle*, *chirimía*, a small mass bell, and the two large bells outside, echoing across the lake, drowned any notes that might have come from the violin.

A procession then formed down the center of the church with Juan at the head. One attendant bore lectern and missal; two others walked backward before him tensing and scattering petals from a tray basket. The procession, with Juan still intoning,

moved to the jars of water by the font. Some of the water was sprinkled, and small nails or thorns were driven into the Paschal candle, as the intoning of the prayers continued. Tinder was burned in a small enamel frying pan to create near fire for the burning of incense. Then the pots of water were blessed, and some white granulated substance, perhaps salt, was placed in each. After that the blessed water, dipped with a small gourd, was offered by Juan to the *cofradia* chiefs. The youths commenced offering it to the rest of the congregation. Many of the girls and young women (the married women, with the possible exception of the *chahalas*, apparently were not at the ceremony) had brought jugs to carry home a supply of the blessed water. When all had been served, the youths carried the remaining pots to the courthouse to be used in the reception there on the following afternoon.

The *cofradia* processions then returned to their respective lodges, where, to judge from the sound of music, ritual dancing started again. The noise of festivity from the lodges continued through the night. Yells and whoops broke out at intervals, and loud protestations from drunks who were being incarcerated came from the direction of the courthouse. At times old men, who were over-inebriated, were led home by the young *alguaciles*. This was often a lengthy business, entailing much patience and tact on the part of the youths, who are forbidden to drink. The old *yen* apparently give lengthy admonitions during pauses on the journey home, and are not interrupted.

On Easter morn the young *sacristans* prepared the church again, arranging the altar as on the previous day. Two masonry platforms, evidently the bases of demolished altars, one on each side of the altar, supported a collection of weatherworn images from church façades or altar niches. Two were especially battered and had broken noses. One could be identified as that of San Antonio, although the child and the arm which held it were missing; the other was supposed to be of San Nicolas, patron saint of village agricultural activities, but which looked more like a statue of San Gabriel. These were removed from the masonry platforms and placed on two frame biers set halfway down the nave, slightly to the right and facing the main altar. From the *sacristy* two bundles were fetched, each containing the vestments of a saint. Under the superintendence of an older man, two youths carefully bound the images to the biers with long strips of white cloth taken from the bundles. Then they arrayed the figures, each with a loose white garment (*alb?*), an old faded chasuble of imported damask, and damask stoles. Red print bandana handkerchiefs were used as headdresses,

that of San Antonio tied in customary Paloponese fashion, that of San Nicolas in the ordinary Indian manner.

When all was ready, the bells rang the summons. The congregation assembled as on the previous day, the *cofrades* in procession with the *teponaztle* at the head, women and children grouped in their place on the floor, boys at mischief everywhere. The councillors carried their new wands.

Juan again officiated. The first part of the service was much the same as on the previous day. The *cofrades* kissed the emblem of San Antonio, palm was distributed, and, on this occasion, the glass case containing the figure of the Virgin was opened, and a palm was placed in her arm. At the Gloria the frayed piece of black cloth, suspended from two long bamboo poles, was withdrawn from the altar.

Then a procession, headed by the saints in their biers, a strong, agile youth to each pair of shafts, formed. A youth strewing petals from a basketry tray led the way. Juan, with his violin, intoned from the missal carried on its lectern by an acolyte. The procession included the musicians, an acolyte with censer, councillors, and the members of the *cofradias*. The young women and children had previously left to obtain seats on the steps of the church. Juan, surrounded by the men, remained on the terrace above the steps; the youths carrying the biers took their places, facing one another, about 60 feet apart, on the road where it widens into a sort of plaza below the church.

Between prayers intoned by Juan, the youths suddenly dashed past each other, tilting the biers at the moment of meeting, so that the two images clashed against each other. This happened six or eight times. After each run the images rested facing one another until the end of the intoned verse. The images were of wood, and met with a resounding crack. In one encounter San Nicolas lost his head scarf. Only the children saw mirth in the proceedings. The youths treated the event as a sport; the men, surrounding Juan, regarded it with solemnity.

At the end of the ceremony, the men re-formed their ranks and departed in procession. The audience dispersed. The images were undressed in the church, and their vestments once more restored to their respective bundles.

That afternoon the *alcalde* and councillors held a formal reception in the *juzgado*. The desk, covered with greenery, was arranged as an altar to hold the new emblem of San Antonio; four tripod censers smoked on the floor in front. The floor was strewn with pine needles brought in large netted bags. The decorated water bars, brought from the church, were against the rear wall of the room. Four beauti-

81.2. San Antonio Palopo: **(a)** the church dominates the village (courtesy of Franz Termer); **(b)** Paloponese; the use of hats instead of tzutes indicates that the party is on a journey, perhaps for the marriage of the pair in the center; note drum, flute, and staff with thong (photograph taken about 1910 by Valdivieso).

ful, modest chahalas knelt to tend the censers. The cofrades arrived in procession to kiss the hand of the alcalde and partake of the contents of the blessed water jars. The drummer and flutist played outside.

I was offered two explanations of the nose-knocking ceremony. One man said in a half-joking way: "San Antonio va a pegar á su mujer. Está borracho como nosotros." (San Antonio is going to hit his wife. He is drunk like us.) A youth, visibly in-

toxicated, said: "Hoy día es día de la resurrección. Nuestros santos van á tomar el castigo antes de nosotros. Ellos son portadores. (Today is the day of resurrection. Our saints are going to take the punishment for us. They are [its] bearers.)" It would be interesting to know whether this is, indeed, an Indianized survival of some ecclesiastical ceremony, or whether it represents some aboriginal feature in Christian guise.

WOODSTOCK, N.Y.

Cuchumatan Textiles: The Course of an Error

Oliver La Farge

A relatively unimportant error is capable of spreading and perpetuating itself in a remarkable way. One such, originally little more than a bit of carelessness, has developed to the point at which published correction is required, having infected not only one of my own publications (La Farge and Byers 1931), but also Dr. Lila M. O'Neale's magnificent *Textiles of Highland Guatemala* (1945). As an example and a warning, also, the story is not without interest.

Among other specimens I brought back from Los Altos Cuchumatanes of Guatemala to Tulane University in 1927 was a San Mateo Ixtatan huipil, somewhat less elaborate than the average. It was the kind of huipil that would usually be made for an older child. Later, after I had severed my connection with Tulane, this collection was shelved in favor of more important exhibits. The label on the huipil must have been lost. Someone relabeled it as from the "Jacaltenango District." Actually the San Mateo Ixtatan huipil bears no resemblance to the Jacalteca.

When Tulane University published *The Year Bearer's People*, an artist was retained, without my knowledge, to prepare an additional color illustration (facing p. 36). Struck by the bright tones of this unfortunate huipil, the artist placed it upon a nondescript figure, and labeled his work of art, "Jacalteca Woman." Unfortunately an erratum slip was not inserted in the book, nor was the label corrected.

This huipil was the only specimen from the Cuchumatan area shown to Dr. O'Neale. She was aware of a conflict in the illustrations in *Year Bearer's People*, where the description of the women's cos-

tume is skimpy and marred by incorrect terminology. Certainly, when confronted by what appeared to be an actual specimen from the area, supported by the most conspicuous illustration in the book, any reasonable person would include it as at least one form of Jacalteca costume. This Dr. O'Neale did, although with reservations ("Textiles," pp. 108, 7.23, 267; Fig. 35a).

A further factor influenced Dr. O'Neale. The correctly identified San Mateo Ixtatan huipils which she saw and described in her book (p. 278; Fig. 38) are choice specimens. One will not see one woman in a hundred wearing garments of this elaboration. The difference between them and the simple example at Tulane is enough to make it seem reasonable that they came from different villages.

The uncertainty created by the situation described above made it possible for Dr. O'Neale to accept another misidentification, a correction of which she has asked me to include in this *Note*. Figure 129f of her book reproduces a photograph taken by A. Biener. Following his information, Dr. O'Neale describes this picture in part as, "Women of Jacaltenango. Tzute worn under straw hat."

The picture may well have been taken at Jacaltenango. The women appear to be either from San Pedro Soloma or from San Miguel Acatan, most likely the latter. The article worn under the hat is not a tzute, but another huipil turned inside out, a common practice at those villages and at Santa Eulalia.

The Jacalteca women's costume is correctly, but amateurishly, described in *Year Bearer's People* (La

Farge and Byers 1931:36–38; Figs. 11, 19, 21). If we delete the mention of the San Mateo Ixtatan huipil, it is also correctly described in *Textiles* (p. 26), although in this description it should have been stated that the use of the Totonacapan cinta is not very common, and that whether the local or Totonacapan cinta be used, the hair is wrapped in the same way.

Four language groups occupy Los Altos Cuchumatanes. Along the southern edge are the Mam, sharply differentiated from the others linguistically and culturally. The rest of the area is occupied by Maya Indians speaking three closely related, but distinct, languages: Kanhobal, Jacalteca, and Chuj.

The Jacalteca costume has been dealt with. The Chuj wear that described by Dr. O'Neale (p. 278; Fig. 38), except that the embroidery is usually less elaborate. The huipil figured by Termer (1930b, Pl. I) is truly typical.

In general the Kanhobal women dress as shown in Dr. O'Neale's Figure 129f, except that the wearing of hats is common only at San Miguel Acatan. In other villages, women seldom wear hats except when herding sheep. My field notes describe the huipil as follows:

"The huipil is a sack reaching almost from wrist to wrist and neck to knee. Typically, it is of white cotton. A yoke around the round neck is [decorated] with black, blue, green, some red and yellow, in narrow lines, zigzags, scallops and chains to taste. [These] are narrow; applique strips. [A drawing shows these forms, plus a stripe of one color from which depends a serrated band of another.]

"Striped and spotted [huipils] are seen; in the fiesta were many of fine cloth, a very few tinted, and one of silk. Ordinarily heavy 'manta' is used, often quite dirty."

"Women turning slightly Ladina, working for Ladino families, mistresses of Ladinos, etc., begin by donning a shorter and tighter blouse,

tucking it in, sashing the skirt and doing the hair in two braids." [The blouse closely approximates the Jacalteca.]

"Maria Juan, Mateo's wife, made a new huipil. First she sewed together the *cantel* sack, then she sewed on a yoke of the same, hemming and gathering both at the neck. Then she stitched on the decoration, of narrow bias tape, being naturally zigzag. She kicked, because she had to use white thread on the dark, and Mateo got her some black. When she had about half the decoration on she sewed a pleated frill of finer cotton on the bottom of the yoke. Up to there the applique had been stitched through both huipil and yoke, from there on, only through the yoke . . ."

"Under the huipil, women wear a short, short-sleeved shirt, in which they often work. Huipils are often worn inside out when working, and sometimes one, thus reversed, is worn as a shawl . . ."

"... Even in this simple costume there is variation between villages, so that women of each village can be recognized. Thus Soloma women use a design [of a straight line of one color with sawteeth of another dependent from it], and Santa Eulalia [a chain design] . . . San Migueleñas use usually only straight and wavy lines, and these wide apart . . ."

Descriptions in brackets in the last paragraph represent sketches in the original. According to this paragraph, my identification of the women in Figure 129f of *Textiles* seems shaky, but they still look like Migueleñas to me.

The skirt is the red-background jaspeado described by Dr. O'Neale for San Mateo Ixtatan. The hair may be wrapped in wool yarn, or in the Jacalteca cinta.

It is hoped that publication of this *Note* will end a sequence of error which has been surprisingly long extended.

SANTA FE, NEW MEXICO

Representations of Temple Buildings as Decorative Patterns on Teotihuacan Pottery and Figurines

Hasso von Winning

Miniature clay temples occur frequently in the Aztec cultural horizon, as well as in western Mexico, but they do not appear in the Teotihuacan period. Nevertheless, the pattern of temple façades has been widely applied by the Teotihuacanos as decorative motifs on pottery and moldmade figurines. Its use has been conventionalized as have many other patterns in this culture period.

A number of selected specimens manifest the gradual changes which this motif has undergone.

The first example to be considered is a cham-pleve tripod vase on which has been incised four times a temple construction, alternating with a Tlaloc face (Fig. 83.1). The temple has been depicted in such a way that all its architectural details are clear and unmistakable. The sloping base, as well as the rectangular wall panels, is characteristic of the classical Teotihuacan period. The stairway in the center ascends to the entrance of the temple chamber. Emphasis is given to the elaborate roof, consisting of beams over the doorway, supporting the typical thatched roof, which, in turn, is crowned by three pinnacles. Thus we have a complete picture of a *teocalli*, and if we compare it with the corresponding designs on the murals at Tetitla (Teotihuacan) of the same epoch (Fig. 83.2), we find that the artist followed an established pattern. Also at Tetitla the roof is out of proportion, being larger than the lower part. In both cases the pinnacles are above the thatch.

The same structural patterns appear on a fragment (Fig. 83.3) from the lower part of a great ves-

sel to which a moldmade application showing a temple was attached. The thatch roof is clearly distinguishable above the doorway. The pinnacles appear in a rectangular frame decorated with knoblike protuberances, probably representing *chalchihuites*. However, these pinnacles differ from those previously discussed, in so far as the one in the center is modeled completely, while only half a pinnacle appears on either side. The spaces between are filled out.

This peculiar pinnacle arrangement is used on the next figure (Fig. 83.4), which is also a moldmade motif attached to the base of a vessel and which alternates with a half-star surrounded by a mountain design. The roof is almost two thirds of the entire motif, but, by comparing it with our Figure 83.1, we are undoubtedly concerned with a temple façade. In Figure 83.5, which was an appliqué, appears a similar representation.

Traces of clay found on the back of Figure 83.6 indicate that it had been formerly applied to the bottom rim of a vessel. It is a similar motif: posts supporting a thatch roof surmounted by pinnacles. This construction rests on a base formed by a panel above a sloping wall. Attention must be called to the fact that the base resembles in all its details the typical nose plaque which appears frequently in relation to figurines and adorned *braseros*. The sculptor ostensibly intended to depict a temple base, but for some reason or other he incorporated in it the pattern of a nose plaque because the center of the temple platform is grooved.

83.1–83.11. Natural size. Purchased at Santiago Ahuixotla, Mexico. Fig. 83.1: Coll. H. Neys; Fig. 83.7: Coll. J. Hauswald; Figs. 83.2–83.6 and 83.8–83.11: Coll. HvW. Drawings by HvW.

83.1. Temple buildings as decorative patterns (no. 1)

This example points to the probable existence of an ideological association between the representation of temple bases and nose plaques.

Figure 83.7 shows a corresponding arrangement in relief on a small bowl decoration. The temple, with raindrops on either side (Winning 1947), alternates with a half-star, a combination we have already seen in Figure 83.4. The design is repeated four times around the rim of the bowl.

If we now analyze the triple motif introduced in the headdress of a moldmade Teotihuacan figurine (Fig. 83.8), we come to the conclusion that the representation of a temple roof is intended. The pinnacles are clearly shown between two parallel beams, from which are suspended vertical shafts representing thatch. Below this roof design is a circle of owl feathers. Superimposed on its lower sector is an ornament like the nose plaque encountered on small clay masks covering the mouth (cf. Linné 1942:171, Fig. 315). The combination of temple roof, owl feathers, and nose plaque has unquestionably a significance for which we have no positive explanation. This combination, however, is not unique, since it appears one above another in the same form on a fragment (Fig. 83.9) which has been a sort of rectangular shield, originally held by a figurine.

The shield or standard is framed on one side by owl feathers.

Also part of a shield, Figure 83.10 shows the same pattern modified. The pinnacles have been replaced by three bosses, the nose plaque is omitted, and the frame of owl feathers has been replaced by a simple line design.

In the headdress in Figure 83.11, the same idea is expressed with the exception of the introduction of a new ornament, a conventionalized flower hanging downwards.

If we compare Figures 83.1 and 83.11, omitting the intervening examples, apparently no correlation of meaning exists between the two. However, by establishing the sequence as presented in Figure 83.12 and analyzing the various interpretations of the temple design, we find it increasingly evident that there exists one basic idea with certain modifications.

On all the figures presented, we find the temple roof placed at the top of the compositions, its logical position. It appears on the ceremonial object (Figs. 83.9 and 83.10) on the upper half and above the feather ring and above the head of the figurine (Fig. 83.8). The accompanying elements, such as the raindrops and half-stars (Figs. 83.4 and 83.7) and both

83.2. Temple buildings as decorative patterns (nos. 2–6).

types of nose adornments (Figs. 83.6, 83.8, 83.9), may signify their relation to the deity to whom the temple was dedicated. Similar deductions have been

made from the codices, where the temples portrayed display certain symbols connected with the god to whom they are consecrated.

The Codex of Tonayan

R. H. Barlow

The Codex of Tonayan, or Plano de San Juan Chapultepec, was painted a short distance north of Xalapa, Veracruz, in the year 1665. What has become of the original is unknown, but it still existed in 1849, when a watercolor copy was made. In 1852 it was copied again, this time in oils, and this second copy survived in Xalapa until at least 1911, after which it disappeared. The 1852 copy was published in a defective halftone by Ramon Mena, in the *Memorias de la Sociedad Alzate* (30:397–402). The 1849 watercolor has not been published heretofore. In order to make available an adequate copy of this lost codex from a region none too bountifully documented, it seems to me advisable to assemble and circulate such material as we have. This material consists of:

1. The 1849 watercolor, preserved in the Mapoteca Orozco y Berra of the Instituto Panamericano de Geografia e Historia, Tacubaya, D.F., and described in Orozco y Berra's (1871:182) printed catalogue of his map collection.
2. A tracing of the 1849 watercolor, made at an unknown date, apparently by someone who projected an edition (Orozco y Berra 1871:183).
3. A photograph of the 1852 oil, that used by Mena for his edition. This photograph comes from documents of Mena's collection which were acquired by Sr. Rafael Garcia Granados, who generously lent it to me. From it four detailed enlargements were made by the Benjamin Franklin Library, revealing everything which can be squeezed out of the Mena photograph, the lower half of which is hopelessly dark (Orozco y Berra 1871:181–87).

The watercolor is more legible than the oil in regard to this murky inferior portion, but does not copy the inscriptions in their places, as the oil does. Moreover, it contains exceedingly careless transcripts of these names, as a brief examination shows. The tracing of the watercolor repeats these virtues and defects in more legible form.

From the three copies, a fairly satisfactory version may be sifted out, since each preserves something the others lack.

The towns mentioned in the Codex of Tonayan are to be found in central Veracruz, somewhat north of Xalapa. Three of them, Chapultepec, Quaquiztintla, and Xilotepec, figure also in the map accompanying the *Relacion de Xalapa* of 1580 (*Papeles de Nueva España* 1905). Chapultepec was independent until conquered by Moctezuma, according to the relation, whereas Quaquiztintla and Xilotepec were subject first to the local city-state of Tlacolula, and thereafter to Moctezuma. Despite their varied histories, both Chapultepec and Xilotepec were bilingual, speaking Totonac and Nahuatl. Since Xalapa spoke "mexicano corrupto" and in Xilotepec there were still memories of pre-Mexican (Nahua?) Chichimec, it is by no means sure that Nahuatl arrived in the region with the Triple Alliance.

The theme of the codex appears to be the usual one of town boundaries and their demarcation. Glyphs 5, 6, and 8 (extreme left of codex) note the arrival of Cortez, depict Moctezuma as former ruler of the region, and refer to one D. Juan Quimich, who may have been Cortez' contemporary. (The glyph of

84.1. Codex Tonayan.

84.2. Codex Tonayan.

84.3. Codex Tonayan.

this cacique, however, reads Michin, fish, and not Quimichin, mouse.) Along with D. Juan are four other principales, with hieroglyphic names only (nos. 9–12). These may be ancestors of D. Juan; they are accompanied by the fabulous figures (60 años, 50 años, 607 años, 607 años) of their rule.

Whatever division of lands was made by Cortez, another must have been effected in 1665. Presumably the Indian governors. D. Andres de Marquina of San Juan Chapultepec (13), D. Diego Xaltuma of San Pablo . . . (14), and Xocoyo(t)l of Tonayan (15), observe his coyote-head glyph, met with three Spanish officials, a nameless corregidor (16), and the two priests, Fr. Alonso de Santiago (17) and Fr. Buenaventura (18) to revise the earlier setup. A good number

of witnesses (19–21) are depicted in the spaces occurring among the place names, and about two dozen figures (mostly in the upper right-hand quarter of the codex) are not explained, beyond bearing name hieroglyphs.

It may be remarked that the Tonayan Codex has a relative in that of Misantra, also published by Mena and now existing in the collection of Lic. Lombardo Toledano, as Sr. Melgarejo informs me.

Only a few of the place glyphs make sense, illegible drawing or inaccurate inscriptions accounting for the vast majority. Coapan (38) is "Snake River" and the drawing is clear. No. 46, Mecaxochitlan, has the glyph of the moon (*meetztli*) and of flowers (*xochitl*), though the element *mecatli* seems to

84.4. Codex Tonayan.

84.5. Codex Tonayan.

84.6. Codex Tonayan.

call rather for a drawing of string or cord. Macuil-xochitlan (34) has the glyph of five flowers, which is to be expected, and has something to do with the Flower God 5 Xochitl etymologically. Pitlaco (27) should be corrected to Patlaco, "Place of Flying." The glyph, curiously enough, is of a winged horse. Nos. 47 (Quaquahutlan) and 39 (Quaquanepantlan) mean "Place of Woods" and "Amid the Woods," respectively, and bear glyphs of trees. Tecamachalco (50) and Tecamachalocan (28) both refer to cave mouths (*tetl*, stone; *camatl*, mouth) and bear crude glyphs of the appropriate sort. Tlaminaloan (30) "Place of Shooting with Arrows" intelligently exploits the St. Sebastian martyrdom. Tzontecomatototlan (48) means "Place of the Bird Head," although the whole bird is portrayed.

The rest of the glyphs, as well as the meaning of human heads, bound prisoners, shields, arrows, and other elements scattered about, are Stygian matters indeed.

AZCAPOTZALCO, D.F.

Elements of Maya Arithmetic with Particular Attention to the Calendar

Charles C. Fulton

Maya (Calendar) arithmetic seems to have had the following well-marked characteristics:

1. Monadic counting and day counts
2. Vigesimal numeration and tun counting
3. Positional notation
4. Use of zero symbols
5. Cyclical time-counting

MONADIC COUNTING AND DAY COUNTS

Maya arithmetic was characterised by virtually complete absence of fractions. No doubt the Maya understood simple fractions such as one-half, one-quarter, and one-third. But quantities, including those we think of as continuous and indefinitely divisible were, for them, strictly counted values of "indivisible" units. This is, indeed, characteristics of primitive arithmetic everywhere. For us the concept of the monad, or "indivisible unit," has almost disappeared, but once it was universal.

The Maya unit of time-counting was the kin, or day. It is generally assumed that this meant a "day" of one complete rotation of the earth, like our "day" of 24 hours. Possibly this is correct, but the assumption has been too lightly made. Nearly all primitive people either count the daylight periods only, ignoring the nights, or (even more often) count the days by the intervening nights. The latter custom was prevalent among the American Indians, and there is some evidence for it among the Maya. It would be a very convenient explanation of certain features of

Maya chronology, if we could say that the days (daylight periods) were *named*, and the nights *counted*. Opposed to this is the meaning of *kin*, "sun," so that apparently the Maya of the inscriptions were counting days, or perhaps sun risings.

The discussion of time-counting by "current time" or "elapsed time" is superficial and often, confusing. These terms suggest our concept of time, something always flowing and infinitely divisible. Primitive people pay little attention to duration. They count time by the *pars pro toto* method, as Nilsson calls it, or by monadic counting, as I should prefer to say, following De Morgan (Nilsson 1920; De Morgan 1850). The question is not when a day of duration began or ended, on which point the Maya may not even have had very clear ideas, but simply when the day was counted as a monadic unit.

One thing is pretty clear: in counting days either forward or backward, the current day, or the beginning day of any period, was not counted. In this the Maya do not differ from us, but they do differ from the Spanish even of the present day, and still more from the Spanish of the time of the conquest. To the French and Spanish, from Monday to Thursday of the same week is a count of 4 days, because they count *one* for the beginning day. To the Maya and ourselves, from Monday to Thursday is *three* days, because we do *not* count the day *from which* the other days of a period are counted. Probably the Maya counted a day as soon as it had begun (become light), but without counting the beginning day. This is just the same as counting the intervening sun risings.

Of exceptional absurdity, it seems to me, is the idea that the Maya, or any other people, ever called today by yesterday's name, as some archaeologists have claimed. The original suggestion, I think, was simply that the day-name and number on a monument might be those for the last completed day; that is, if the monument bore, for example, the date 6 Ahau, the celebration, the feast of dedication, etc., may have been really held on the following day, 7 Imix. This is not altogether irrational, although suggested by the "elapsed time" illusion, the idea that the Maya never *counted* a day until it was *over*. I know of nothing to sustain it. I think it clear enough that with respect, for example, to 9,11.0.0.0 6 Ahau 13 Muan, Ahau was the cyclical day, the round-number date was also the cyclical day, and the feast and the taking of the fates, the shifting of the idols in the temple, and so on, were on that day.

VIGESIMAL NUMERATION AND TUN COUNTING

The regular Maya numeration was by powers of twenty, with a distinct name for each vigesimal order. In most languages the names of higher orders are frequently compound, e.g., our "ten-thousand" and "hundred-thousand."

In the Maya calendar the unit period was the kin, or day; 20 kins made a uinal, then 18 instead of 20 uinals made a tun. The tun of 360 days was no doubt considered the theoretical or ideal year. As a closer approximation to the true year the Maya also recognized a period of 365 days, obtained by adding 5 "useless" days to the tun. The calendar of month-dates employed this invariable 365-day year. Other ancient nations, the Egyptians and the Babylonians, also considered 360 days to be the "ideal" year and added 5 "useless" days to come closer to the real year. There were two differences from Maya practice. The ideal year of the Egyptians and Babylonians consisted of 12 months of 30 days each, instead of 18 "months" of 20 days each. (Thureau-Dangin 1939). And the ancient nations generally counted more or less by actual years, most of them by luni-solar years, the Egyptians by invariable years of 365 days each, but the Maya counted longer periods by their ideal "years" (tuns) of 360 days each.

An interesting peculiarity of old Maya oral numeration is said to be that after 40 the count was usually "on" the following score; i.e., 41 was "one on the third score" (60), etc. In line with this, the Maya, it seems, generally looked forward to round-number dates, and gave other dates as "going on" the next exact tun-number, the next katun-day, etc. I cannot see that this is a matter of naming periods of

time for their *ending* days, as claimed by virtually all archaeologists at present. It was simply a matter of looking forward rather than backward for a convenient reference date. It was similar to the child looking forward to his birthday anniversary and saying, "I'm six years old, going on seven." Sixty is threescore, not *the end* of threescore; three o'clock is the hour, rather than *the end* of the hour; and 9.0.0.0.0, in my opinion, might better be called simply Baktun 9, rather than *the end* of Baktun 9.

POSITIONAL NOTATION

Apparently only the Maya ever developed a system of written positional numeration independently of the invention of our present decimal notation in India and its spread throughout the world.

Because the value of our decimal notation is and has been enormous, the Maya achievement is likely to be over-stressed. The Maya positional system was in the main a rather sorry thing. On the monuments, with one or two exceptions, the numerical values were not by place alone, but were spelled out by means of glyphs for each of the periods involved. In the same way we commonly write any denominate number, for instance "4 rods, 12 feet, 3 inches." It is like having to write out a number as "7 thousand, 4 hundred, 6 tens, 8 units."

It is true, in the codices the Maya did give numerical values for calendric periods by place-value alone. But the system cannot have been of much use for purely arithmetical purposes: it had been spoiled in the making by the irregular, non-vigesimal jump, 18 uinals = 1 tun. In favor of the Maya achievement it is urged that they had the most important essential of a positional notation in having a symbol for zero.

Contrary to the usual statements, a positional notation and the concept of zero are not absolutely inseparable. I shall not stop to prove it here, but it is possible to have a strictly positional notation, not altogether different from our present one, without any zero whatsoever. It does not quite conform to ordinary custom in counting, however. To be sure, the Maya as well as the Hindus did make "zero" an integral part of their plan of positional notation. My remarks here simply mean that to some extent we must analyze these ideas separately. I think we may say that in having any concept of a symbolic zero the Maya were surprisingly advanced, but their positional notation in itself was scarcely more than rudimentary. Their other great achievement in Long Count dates was in having a definite era so early in history. This idea was missed almost completely by the ancient empires of the Old World in times B.C.

Accept, however, that the Maya had a true positional notation, as finally proved by the use of the positional zero. How did they come to think of it? What did they have in common with the Hindus that other people lacked?

Positional numeration is not quite, such a pure inspiration as generally assumed. Many ancient nations had it on the abacus, but without realizing its possibilities. The Hindus set up their notation to record the results of abacal computation, with 0 for an empty column. Apparently the Maya did the same kind of thing, in even simpler fashion, with the board turned for division by rows instead of columns. Their numbers may represent actual sticks and pebbles, perhaps merely laid in places marked on the ground. However, it is very likely that a shell was actually present for the "zero," quite probably the Maya calendric zero does not represent the idea of vacancy, as does the Hindu symbol.

An important factor in the step taken by the Hindus seems to have been that they had a distinct name for each decimal place (Smith and Karpinski 1911). The Maya, in comparison, had a distinct name for each vigesimal period, and also for each time-period in their modified vigesimal system, without anywhere exceeding the vigesimal scale. This, it seems probable, must have been the factor that facilitated the advance made by these two peoples only, from abacal computation to a purely numeral, written, positional notation.

USE OF ZERO SYMBOLS

The Maya had several different symbols for "zero," and actually two different kinds of zero, or glyphs which have been translated "zero." The positional zero was represented in several different forms, the one most commonly used in conjunction with the bar-and-dot numerals being a glyph representing a shell. Besides this they had a symbol, the "spectacle" glyph, for the beginning day of the month. This is also transliterated as 0, since the next day was numbered 1, with the same month symbol. There is no evidence that the Maya saw any definite connection between these two kinds of "zeros." The difference between them is apparent in the fact that the positional zero or cipher never stood alone numerically, whereas the spectacle glyph always did.

In the history of our own notation, most educational theorizers held, until quite recent times, that the "cipher" had no significance by itself, and could not be used alone, but only when preceded by some significant digit. On the other hand, even at the beginning of its history some of the Hindus had been able to connect the symbol for the vacant column of

the abacus with the general idea of "nothingness," "the void." Eventually the concept of zero as a number developed, becoming definite with Stevinus.

I don't know whether the Maya had any idea at all of a "cardinal" zero meaning "nothing." Their arithmetic for cardinal counts of cacao beans, flint knives, etc., is virtually unknown. We have only their calendar arithmetic in written form. Even assuming that in both cases the numbers finally used were taken from the abacus (and this is assumption, for our certain knowledge of any Maya abacus is almost nil), we find that it is entirely possible that in calendric calculations a "zero" row was not vacant, but held a shell. It is probable that the Maya concept of such a zero was cyclical, "return to the starting point," not the idea of "nothing."

The Maya "Long Count" ran from 4 Ahau 8 Cumku as Beginning Day or "Zero Day." The latter designation is correct for our present way of thinking, but the Maya did not represent it by a "zero" symbol. To them it was (as translated) the "end" of Baktun 13; it would be less misleading in English to say the cyclical consummation of Baktun 13; the cyclical date 33.0.0.0.0, from which the next long round of days was to be counted.

A Long Count number is now generally regarded as the cardinal number of elapsed days that had passed since the chosen 4 Ahau 8 Cumku. This implies an idea of duration, flowing time, which I doubt the Maya felt. The Long Count concept I think was really ordinal-cyclical; a Long Count number showed the place of the day in the cycles of baktuns, tuns, uinals, and kins, by a count of kins from 4 Ahau 8 Cumku. The zero was a cyclical ordinal, rather than a cardinal number.

The symbol for the zero day of the month it is possible to interpret as a true absolute zero if we assume that the Maya were really counting the intervening nights. In that case spectacle-glyph Mol, for example, would mean that the day belonged to the month of Mol, but no nights of Mol had yet been counted. I distrust this interpretation if it is supposed to mean that the Maya meant the spectacle glyph to represent an absolute zero. However, I think it quite possible that the Maya numbering of the days of the month may have been adapted from an original count by nights. From one feast-day 20 nights or "sleeps" were counted, then came the next feast-day. If the feast was considered to pertain primarily to the following rather than the preceding month, the day would take its place in that month, preceding the day numbered one.

The evidence in regard to this "zero day" of the month seems to me fairly clear. The same day belonged to two consecutive months, and could be

designated either as the completion of the one, or as the beginning (the zero day) of the next. There is an affinity of ideas here to the concept of the cyclical-positional zero of the Long Count, but it is not necessary to assume that the Maya made the connection. It shows how they thought, however, and strengthens the cyclical interpretation of the positional zero. J. Eric Thompson thinks the spectacle glyph should be translated "the seating of," referring, I presume, to the enthronement of the deity of the month. It seems to me that this excellent translation is fully in accord with the meaning "beginning day" of the month, or in our terms, "zero day." This zero beginning day was at the same time the ending day of the preceding month; a commonplace of cyclical counting, however odd it may appear to us. The ancient Athenians also had a day common to two consecutive months, lunar months. They called it "old and new," as pertaining to both the vanished and the reappearing moon.

CYCLICAL TIME-COUNTING

We have little use for the idea of cycles any more; we have adopted the idea of the infinitely serial instead. Our still-used cycle, the week, is not the subject of calculation; we look at a calendar instead. How many people realize that dates in October as compared with those in September are advanced two days in the cycle of the week, because the number of days of September (30) exceeds the nearest multiple of 7 by 2? or that September 10 (say) is one day earlier in the cycle of the week than July 10, because 62 is one less than the nearest multiple of 7? Somewhat similar calculations were doubtless commonplace to the Maya. The unequal lengths of our months and years have tended to discourage such calculations.

The peculiarities of counting when applied to cycles are not well understood by most people. The end of one period is the beginning of the next, the turn of the cycle. If a time cycle is analyzed down to "instants," this common element may be infinitesimally short, "a point of time." But this is not necessarily so. The common element for successive time-cycles can be a day, a year, or any other element counted monodically. The monadic unit of Maya time-counting was, of course, the kin.

Not only is the end of one cycle the beginning of the next: to count through one complete cycle by itself, one element has to be counted twice, that is, both at the "beginning" and the "end." This is equally true whether or not a zero is used. The Romans had no zero and counted the cycle of the week in days from 1 to 8, as, indeed, the French and Spanish still do. The eighth day is the first over

again, and becomes a new first. In the same way we still number the seven different notes of the musical scale from one to eight. However, our usual custom is now different. Mathematically we designate the beginning element with zero instead of one, then count to the number of the cycle, which is equivalent to zero again. The cyclical element, on which the cycle "turns," is explicitly numbered 0, or alternatively given the number of the cycle, which is equivalent to zero for that particular cycle.

People in general, in this country, now usually count "one" for the next element *from*, or *after*, the starting-point. Usually they are unconscious of their implicit zero; the starting-point is simply "not counted." Our numbering of the days of the week is somewhat confused by vestigial recollections of Roman counting. However, we commonly count forward from a day without counting it, but counting the next day as "one." The Maya did the same, and other peoples, too, have counted days or years in this way. The wonderful thing in the case of the Maya is that they ever made their "zero" explicit and devised written symbols for it. Their zero beginning was not always explicit but sometimes it was, with a cyclical or "ending-beginning" meaning.

The "zero day" of the month is a remarkably explicit example of the same day being both "end" or probably better "completion" of one month and "beginning" or "the seating of" the next. In the codices the starting day of a series of calculations may be omitted, taken for granted, or "not counted," then when the calculations have carried through a cycle one finds at the end the same name of the day from which the start of the count was made. This is an example of counting from a non-explicit cyclical zero. Further, the Maya often used 13, or 20, as a cyclical zero. Goodman nearly realized this at the start and declared that the Maya counted "20, 1, 2, 3 . . ." etc. However, he apparently did not fully understand the characteristics of cyclical counting and later decided that what he had taken for the beginnings of periods were "really" ends.

Cyclical change is well represented by a curve rising from a horizontal line, then falling below it and rising again, and duplicating itself repeatedly. Now consider one cycle of the curve by itself. It extends from a point at which it rises from the horizontal line to the next point at which it again rises from the line. Suppose we select eleven other points in between, on the curve, as also representing important elements to be numbered. Then in the Roman system the point on the line where this cycle begins is numbered 1, the other points 2, 3, etc., to 13 for the next point on the horizontal line at which the curve rises again, 13 being also a new 1. In mod-

ern mathematics the same points will be numbered 0 to 12, 12 being also a new 0. There are only 12 *different* elements, but if we number them 1 to 12 or 0 to 11 and stop there, we have not represented the complete cycle, since we have not yet reached the element at which the curve begins to repeat. Now the Maya would have numbered such a cycle "12, 1, 2, 3," etc., to 12 again, beginning with the ending-number of the "preceding" cycle, whether or not a preceding cycle really comes into consideration. A mathematician might do that today. In fact, we even have an example of such numbering in common use, 12 o'clock midnight as the *beginning* of the day.

The Maya counted about as we do, but were much more familiar with cycles and cyclical counting. Probably much confusion has resulted from attempted explanations by Spaniards, who counted in a different way. Indeed, the Spanish-educated Maya after the conquest cannot have understood their own ancestors, and added to the confusion. There is the possibility also that some changes in Maya counting had already occurred or were under way, owing to Nahua influence, dust before the Spaniards arrived on the scene. To the old Maya the *first* element, so counted, numbered 1, was the first *from* or *after* the starting point, or the *first completion*; to the Spaniards the first was the starting-point, or the *first beginning*. We ourselves are sometimes a little confused about this, due to survivals of the old mode of counting; for our Teutonic ancestors counted in the same way as the Romans, except that in time-counting they usually counted intervening nights, instead of days. As one result we frequently have a discrepancy between our cardinal and ordinal numbers. This is often assumed to be unavoidable; but most of the supposed necessity of the confusion is imaginary. If we agree that when we start from zero, whether expressed or only implied, then "one" or "the first" means the first element from or after the zero starting-point, or, in the case of continuously growing or flowing magnitudes (e.g., duration of time), the first completion rather than the first beginning then cardinals and ordinals will correspond again, as of course they ought to do.

To call the cyclical "turning" days of the Maya "period-ending" dates, as all archaeologists now do, is awkward, unnecessary, and sometimes inexpressibly confusing. "Period date" would do as well, or, even better, "cyclical date" or "round-number date."

I now state some brief conclusions without further discussion. In the cycle of numbered days, 13 was the cyclical number, Ahau the cyclical day-name. 13 Ahau was the turn of the cycle of 260 days; 1 Imix was the first day from the cyclical starting-point. 13 Ahau was also one of the katun-days and the turn

of the cycle of the katuns. Counting a katun of days from this day one comes to katun *day* 11 Ahau, which was consequently the first completed or (better) first counted katun. The cyclical days of the Long Count were, of course, the round-number days.

The Roman rule was, "the end of the old is the first of the new." The Maya rule was, and our modern rule, as regards cycles, is, "the cyclical completion or 'ending' of the old is the beginning or zero of the new."

CYCLICAL CALCULATIONS

The simplicity and ease of cyclical calculations are not as well known as they might be. The place of any number in a cycle is not changed by adding or subtracting the number of the cycle or any of its multiples, since these are equivalent to zero. Any number can be conveniently designated forward or backward from the cyclical turning point, by the positive or negative difference from the nearest multiple of the number of the cycle.

For example, in the Maya system the passage of one uinal advances the day number by 7. Considering the cycle of 13 day numbers, we have:

1 uinal	= 20 kins = 20-13 = +7 (or, 20-26 = -6)
2 uinals	= 2 × 20 = (2)(+7) = +14 = +1

That is, the day-number gains 1 in 2 uinals.

18	= 18-13 = +5
1 tun	= 18 uinals = (+5) × (+7) = +35 = 35-39 = -4
1 katun	= 20 tuns = (+7)(-4) = -28 = -2
1 baktun	= 20 katuns = (+7)(-2) = -14 = -1

Consider a Maya Long Count date, such as 9.17.13.8.5. What is the day number?

From the calculation at the right,	(9)(-1) = -9
the day number is back 1 from 4 Ahau.	(7)(-2) = -1
Since the kins read 5 the day is	(13)(-4) = 0
3 Chicchan.	(4)(+1) = 4

The same kind of calculations can be applied to any other length of cycle. Generally they can be carried out mentally for reasonably short cycles.

A little more difficult to handle is a longer cycle, such as the Maya year of 365 days. In Maya terms this is 18 uinals 5 kins, or 18.5, which is the equivalent of 0 for the cycle of the year. (The point . between 18 and 5 of course is not a decimal point but a vigesimal scale mark; all numbers are integral.)

1 tun	= -5 kins on the cycle of the year
1 katun	= 20 tuns = 20 (-5) = -100 kins = -5 uinals = -5.0
1 baktun	= 20 katuns = 20 (-5.0) = -100 uinals (add 6 years; i.e., 108 uinals 30 kins), 1 baktun = 8 uinals 30 kins = +9.10
2 baktuns	= +18.20; subtract 1 year (-18.5), 2 baktuns = +15 kins

Take the date previously given, 9.7.13.8.5:

8 baktuns	= (4)(15) = 3.0
1 baktun	= 9.10 (obtained from 36.10 (2 years)—35.0 = +1.10)
7 katuns	= (7)(-5.0) = 1.10
13 tuns	= (13)(-5) = -3.5
	+ 8.5 = 18.20 = +15

That is, the year date has gained 15 days on 8 Cumku; it must be 3 Uayeb.

Within the year dates can be represented in the same way: 18.5 can be taken as 5 Uayeb, the end of the year, which is the same as 0 Pop, the beginning and zero day of the year (numbered 0.0 or just 0); 1.0 is Pop completed or Uo begun; 8 Cumku is 17.8; 18.0 is Cumku completed or Uayeb begun, etc.

Let us solve for example 12.16.0.0.0:

12 baktuns = 6(15) = 90 kins	= 4.10
16 katuns = 16 (-5.0) = -80.0 + 90.25	= 11.5
(5 years)	15.15
We can add this to 8 Cumku (17.8)	17.8
	32.23
And then subtract out the completed year	-18.5
	14.18

Date is 18 Muan.

(or, we could subtract a year from 15.15; that is, 15.15 = -2.10, which tells us that we are to go *back* 2 uinals and 10 kins from 8 Cumku: 17.8—2.1.0 = 14.18; date is 18 Muan.)

Such calculations can still be made mentally, or with very slight assistance from pebbles or grains of corn, especially when the equivalents for various numbers of tuns, katuns, and baktuns have been memorized; e.g.,

7 katuns	= + 1.10
14 katuns	= 2(1.10) = + 3.0
28 katuns	= + 6.00 = 1 baktun 8 katuns, etc.

I have little doubt that the Maya experts calculated in just about this way. Of course they did not have our concept of positive and negative numbers, and probably multiplied merely by repeated addition. However, the + and—signs simply mean “go forward” and “go back.” Calculations only slightly simpler should even be within the powers of the modern Maya.

ACKNOWLEDGEMENT

I wish to express an initial indebtedness to Richard C. E. Long, Maya and Christian Chronology, *Journal of the Royal Anthropological Institute* 53:4–41. 1923. I am also greatly indebted to personal correspondence from J. Eric Thompson.

ST. PAUL, MINNESOTA

NOTES

1. Charles C. Fulton (1900–1992) was a pioneer in the development of non-aqueous media for microcrystal tests for drugs. His career commenced in the era of Prohibition and his record of publications began when forensic science literature as such was non-existent. His efforts in drug identification led him to develop many new reagent media, keep pace with the rapidly expanding number of drugs in the post-war era, and contribute his science to combating international drug trade by identifying opium sources for the newly created United Nations Secretariat. He authored *Modern Microcrystal Tests for Drugs* (1969), a text still used in many forensic science laboratories, before retiring to pursue eclectic interests including publishing on archaeoastronomy, particularly of the Maya.

Certain Types of Stamped Decoration on Pottery from the Valley of Mexico

Hasso von Winning

In discussing a collection of pottery from Texcuaco on the Rio Coyolate, Department of Escuintla, Guatemala, Dr. A. V. Kidder (Note 15) refers to a vase which bears two rectangular panels, impressed by the same stamp (Fig. 86.1.1). Each panel is outlined, after stamping, with an incised line. Near the base are three small heads, made in the same mold and luted to the wall. The ringstand or pedestal base has been broken. Precise data as to the provenience of this specimen are lacking. So far Dr. Kidder's commentary. For reasons of harmonious composition the panels are stamped in such a way that one has to turn them to the left to perceive the design, which depicts a human face surrounded by what appears to be the head of a serpent, whose upper jaw covers a human head. The serpent's eye is depicted vertically adjoining the earplug. The rest of the motif consists of scrolls, done in a flamboyant manner which strongly suggests Maya Old Empire style.

Since the decoration was done by means of a stamp, this specimen can be considered as belonging to the group of sculptured vessels. According to Lothrop (1936a), this type of pottery falls into two major groups: those carved before firing and those carved after firing. Further, there are various combinations of the technique. In Figure 86.1 the decoration must have been applied while the outer surface of the clay was soft.

A vessel with an almost identical design executed in low relief has been recently purchased by the writer at Santiago Ahuixotla, in the Valley of Mexico. It is a bowl with rounded bottom and four

identically stamped panels (Fig. 86.1.2). No incised lines frame the panels; the edges, however, were sharply cut after the impression was made. Each convex panel is flanked by a groovelike depression. The relief is not very deep, yet the details are clearly distinguishable. The yellow-brown color of the clay, the brown slip, and the stick-polishing on both sides suggest that this vessel falls in a post-Classical period of Teotihuacan. The dullness of the stamped-out panels contrasts with the polished surface of the undecorated parts.

The position of the decorative pattern is the same as that of the Guatemala vessel; that is, one has to turn it to the left to recognize the motif. The serpent's jaw is opened wide and frames a human head. On the Guatemala vessel (Fig. 86.1.1) there is a short speech-scroll in front of the mouth of the priest or god, whereas the Ahuixotla specimen shows a sinuous detail, representing a tooth or teeth, set in the mouth. The same details denote the serpent's incisors on both the upper and lower jaw. The supraorbital plates of god and serpent are identical in design. From a large scroll there emerges what seems to be a human extremity.

This composition is almost duplicated by a fragment found by Linné at Teotihuacan (Linné 1934, Fig. 130-A). Although incomplete, the Teotihuacan sherd exhibits enough details to make possible a comparison, and the foregoing specimens prove the correctness of Linné's explanations. He classified his find as "Maya style" and compared it with a vessel cover from Ranchito de las Animas, which

86.1. Mexican pottery with stamped decoration: (1) vase with two rectangular panels, impressed by the same stamp; from a collection of pottery from Texcuaco (Rio Coyolate), Guatemala; (2) stamped design that appears four times on a bowl from Santiago Ahuixotla, Mexico; diameter 19 cm, height 8.5 cm; panel natural size.

Strebel remarked might have come from another region (Strebel 1885–1889:69). Furthermore, Linné sees analogies in the Teotihuacan sherd with the once famous relief vase from San Agustín Acasaguastlan, Guatemala, to demonstrate the Maya origin of the sherd. This comparison, however, can no longer be sustained, since doubt about the authenticity of the Acasaguastlan vase has been substantiated (Thompson 1942). Yet the similarity to the other relief-decorated fragments found by Linné at Teotihuacan points strongly toward Maya origin.

The concept of combining a serpent with a human head set in its jaws is manifested in Maya art where it represents the final steps in the evolution of the divine serpent (Spinden 1913). Figure 86.2.3 shows an example in stone sculpture from Yaxchilan, in which a human head is placed in the distended jaws. (cf. also Codex Nuttall (1903:69); the “Quetzalcoatl motif” at Chichen Itza and at Tula; and the heads set in the xiuhcoats of the Aztec Calendar Stone.)

Figure 86.2.4 is a stylization of the foregoing patterns. The serpent's head is completely conventionalized and resolved into scrollwork. By comparing Figures 86.2.4. and 86.1.2, one can recognize the serpent's features without fear that imagination has led one astray. The center of the composition is the eye. The large scroll next it, also found in Figure 86.1.2, indicates the joint of the jaws. The human face is missing in Figure 86.2.4, but is replaced by scrolls. Another scroll, representing the serpent's nose, is found on all specimens. The style suggests Totonac influence.

The panels of Figure 86.2.4 are impressed four times on a bowl of the same shape as the one in Figure 86.1.2. Both specimens have the same provenience, paste, and finish; the relief is flat in Figure 86.1.2, deeper in Figure 86.2.4. In getting the pattern out of the small mold, the sculptor must have had difficulties which induced him to correct afterwards certain minor details, thus creating in the different

86.2. Mexican pottery with stamped decoration: (3) serpent's head with human head between its jaws; stone sculpture from Yaxchilan; (4) stamped design that appears four times on bowl of same shape and size as Fig. 86.2; from Santiago Ahuixotla; panel enlarged to double size.

panels slight discrepancies which become evident only after careful comparison.

Following the sequence of the various forms of representing this human-head-in-serpent-mouth conception, we find the same idea expressed on another carved vessel, also discovered by Linné at Xolalpan, a suburb of Teotihuacan (Fig. 86.3.6). The technique of the carving is a different one, since the Xolalpan vessel was carved after firing and thus belongs to the champleve group. Linné referred to the design as a "highly stylized animal figure, of which, with the exercise of some imagination, the head can be made out to the left, the tail to the right, and the legs below" (Linné 1934:62). From what we have seen so far, we can deduce that the Xolalpan vessel actually represents a highly stylized serpent's head. Eye with eyelids forms the central motif. To the left protrudes the upper jaw with a row of teeth. The nose is not very clear, but the two greenstone beads, which I do not believe have numerical meaning, seem to belong to it. They also appear on Figure 86.1.2 in the same position. Whether the scrolls on the bottom

and at the right side represent the animal's legs and tail, or whether they are carved to fill out an empty space which should have been taken up by a human head, is an open question.

In Figure 86.3.7 we have grouped details of the eye with its supraorbital plate and the upper jaw with teeth belonging to the serpent.

The technique of carving pottery was well developed by the Maya before the end of the Old Empire. This type of pottery has a wide distribution but has not been found at any single site in large quantity, except recently at Tajin (du Solier 1938), where, by means of its peculiar decoration, "the 13 rabbit glyph," it is definitely related to the Temple of the Columns. Yet this type of carved ware is remarkably different in style and technique from all the specimens discussed in this paper. The center of champlevé pottery apparently was Teotihuacan and the vicinity of Azcapotzalco.

In connection with this head-in-serpent decorative motif, it is appropriate to discuss another type of relief-decorated ware which is also found in the

86.3. Mexican pottery with stamped decoration: (5) detail of tattoo markings on stone head, Totonac style; identical facial decoration appears on both sides; (6) stylized serpent's head; carved motif on champlévé vessel from Xolalpan, Teotihuacan; (7) details of the serpent's eye with its supraorbital plate and, in the second row, the upper jaw with teeth; (a) plumed serpent, Chichen Itza (after Spinden); (b) Guatemala vase (Fig. 86.1); (c) Ahuixotla bowl (Fig. 86.2); (d) Ahuixotla bowl (Fig. 86.4); (e) Xolalpan vessel (Fig. 86.6).

Valley of Mexico and which seems to be coeval to the Teotihuacan culture. These vessels are of a yellowish clay, slipped slightly darker on the inside, and are well polished. The decoration is stamped, usu-

ally three times, in panels. The rim and panel separations are highly polished red bands. The relief is unpolished and not sharply outlined, so that details are not always clearly separated from each other.

86.4. Mexican pottery with stamped decoration: (8–11) potsherds showing moldmade relief decoration on red-rimmed bowls with rounded base; Santiago Ahuixotla, Mexico.

86.5. Mexican pottery with stamped decoration: (12–14) potsherds showing moldmade relief decoration on red-rimmed bowls with rounded base; Santiago Ahuixotla, Mexico.

The designs represent a human face of a somewhat fantastic expression, crowned by a large headdress, probably an animals head. Other parts of the body are composed of scrolls and sinuous details.

Figures 86.4.8–86.6.16 show a variety of specimens of identical texture, all expressing the same pattern with variations. The source of this type of pottery might have been the Valley of Mexico, but the pattern seems to be of Totonac origin. Perhaps in this case only the molds were imported. One may make this assumption, since a similar design (Fig.

86.3.5) appears as facial decoration in relief on a flat stone head (*hacha*) of typical Totonac style in the Cranbrook Academy of Art (Exhibition 1940:47).

CONCLUSIONS

Out of the variety of relief-decorated pottery there appear two types in the Valley of Mexico during the post-Classical Teotihuacan period, which show patterns developed by other cultures but applied on vessels made in the valley. Both types of decoration are

86.6. Mexican pottery with stamped decoration: (15) panel design repeated three times on complete red-rimmed bowl (Collection American Museum of Natural History; I am indebted for the tracing to Dr. Gordon Ekholm); (16) panel design repeated three times on complete red-rimmed bowl; natural size (Collection H. Neys).

impressed by stamp. These were, perhaps, imported. The method of decorating pottery in relief is widespread in the Maya region. The designs of the two types herein discussed show a head-in-serpent motif and a head-and-scroll-work motif, both applied two, three, or four times in panels. The head-in-serpent motif is a Maya Old Empire pattern. It is also found in the Mexican highlands during the post-Classical period of Teotihuacan; it was adapted in a simplified

manner as freehand design on champléve pottery of this period and later was continued by the Aztec.

The head-and-scrollwork motif suggests Totonac influence. The sinuous details are characteristic of the style of this culture. The appearance of a stylistically related design on the face of a flat stone head known to be a typical Totonac *hacha* supports this assumption that the motif in question is of Totonac origin.

MEXICO, D.F.

Observation of the Sun among the Ixil of Guatemala

R.C.E. Long

Through the courtesy of the Division of Historical Research I have been able to see the microfilm of the notes on the Ixil by the late J. Steward Lincoln (1946). Appended to it is a diagram entitled "So-called sun observatory. Nebaj. Stone markers extending from behind Campo Santo up to top of high hill west of town. From Campo Santo to top approximately 1 1/2 km. Sun rises on lines a-b and x-y observed from stones O and P, on March 19, 1910, 2 days before the equinox. Sun rose this day at 6 degs 31 1/2 ms. Direction observed with simple *adjustable* compass. Observations of the sun are made at the stone today by zahorins for planting and harvesting." The foregoing is a copy of Lincoln's manuscript note as far as I can read it, which is difficult; I am doubtful if I have correctly read the words and figures [italized]. I can find no reference to this elsewhere by Lincoln except that in listing the ancient remains of the district he includes "stone temples with steps, a sun observatory (have drawn this from Nebaj)."

Unfortunately, he gives no information as to the procedure in taking observations or who takes them. His diagram shows the outline of the hill, the position of the sun at sunrise over an indentation in the hill, and a line extending from O to this indentation. On that line at a considerable distance from O there is a stone through which the line passes. No doubt this stone is used by the observer to take a sight along the line when he makes his observation from O. A similar line connects P, and the indentation and a similar stone is on this line by which to sight along it. Evidently for greater accuracy two persons must

observe the same indentation at the same time from two different points. The Hopi Indians have a similar procedure but only one observer. The diagram shows other stones scattered about some have short lines connecting them with a line running from the sun to a stone circle between the two above-mentioned lines, from O and P to the sun. These short lines are given no explanation, compass bearing, or date. It is very unfortunate that we are not told whether or not any of the other stones are used for observation. Calculation shows that 19 March 1940 was the day 1 Kan in the Ixil calendar.

The Hopi have no definite day-to-day reckoning but only a fluctuating luni-solar year about which they themselves differ in opinion; they have, therefore, no means of obtaining accurate points of time in the tropic year by counting days. Nevertheless, as they take a large number of observations (probably about twenty or so), each at the appropriate time of the year, they can in practice fix very accurately the dates in the solar year required for their work (Forde 1931).

It is evident, of course, to us that as the Ixil have an absolutely accurate count of days, it would be quite sufficient if they observed the sun once a year, say on 19 March, as they could then fix the dates of other occupations at so many uinals and days from that. But perhaps it may not be so obvious to them as it is to us, and this makes it most unfortunate that we do not know if they take more than one observation a year. The choice of the day 19 March is no doubt owing to its being near the vernal equinox; perhaps

the choice of the exact day is due to there being a convenient indentation in the hill, from which to take observations. The Hopi observations are of sunrise at various named marks on the mountain.

All the known calendars still in use in Guatemala show certain day names favorable for planting. Charles Wagley (1941) says that at Santiago Chimaltenango it is so important to plant on the proper day that they work very fast in order to have the whole field completed on that day. Concerning a planting of corn which he saw done among the Ixil, Lincoln says they all worked fast and finished that day, though he does not connect this with the need to complete on a favorable day. However, his list of day names shows A'mak, favorable for cornfields and the "milpa blanca"; I'q, favorable for sowing corn; Kamel, favorable for the yellow milpa, and Kanil, day of the holy milpa, favorable for all other seeds and planting. He does not give the date on which he saw the planting done but mentions (probably a day or two afterwards) that he asked if the turkey being fattened would be sacrificed next Sunday, 7 Noj. Now 7 Noj was a "chief day" and fell on Sunday, 20 April 1940, so his question was asked on any of the days from 13 to 19 April inclusive (13 Tchii to 6 A'mak in the Ixil calendar). It is very probable, therefore, that the planting he observed was on the favorable day 11 Kanil, 11 April 1940. That would be one uinal and three days after 19 March, so the rule might be to plant on a favorable day falling after the expiration of one uinal from 19 March, the day of observation. The tachbal amak (former months) are now confused and not correctly remembered, but when they were functioning it would have been quite easy to note the observation of the sun and to give one of the month names (e.g. Tacaxipual, see below) to the month in which this occurred, even if it involved a break in the order of the months. It would have the effect of intercalating a month at that point to correct the calendar. Then any other work to be done in the year could be fixed as being in such and such a month. It seems probable that the zahorins nowadays either remember the tachbal amak but keep the knowledge to themselves as a useful business secret, or else know how to count so many uinals and days from the day of observation of sunrise at the stones.

An indirect confirmation comes from an unexpected quarter. Emeterio Pineda (1845) does not correlate his list of months with the Christian calendar but on page 11 he says that the natives sowed in the month Olalti, whatever the state of the weather was, and that if the crop was lost, they did not sow in any other month even if the weather was suitable. But according to Schulz (1942), the Tzeltal month Olalti at present begins on March 16. This would quite

well fit my hypothetical rule above. However, he also says that the Tzotzil month Olalti now begins on April 11, which would still agree with planting on the favorable day. It has been thought that the Tzeltal months have been frozen into the Christian calendar. That would dislocate any relation to the ancient shifting year; but, as I believe, and have for a long time contended, that the times of feasts and farm work were fixed as necessary by observation without disturbing the rotation of the shifting calendar (Long 1937:98), it is then natural to conclude that the frozen dates are in fair agreement with the Christian year and the true tropic year. Of course, once they were frozen they would keep right by agreeing with the Christian calendar.

The best evidence we have of correction by observation in preconquest times is the statement of Motolinia (quoted by Maudslay, "A Note on the Position and Extent of the Great Temple Enclosure at Tenochtitlan") that the sun was supposed to rise at the vernal equinox between the two temples of the Great Pyramid at Tenochtitlan at the feast of Tlacaxipeualiztli, and that Montezuma wished to pull down the temples because the line was not quite straight. It will be noted that in this case, too, the year was fixed by the vernal equinox, a time near the most important season of the year, that of planting corn. In addition, as Merrill (1945) has shown, it is much easier to observe the position of the sun at the equinox, when the sun moves swiftly, than at the solstice, when it is nearly stationary for some days. It is also noteworthy that both the Quiche and the Cakchiquel, although most of their months differed, had a month Tacaxipual corresponding in name and date with the Aztec Tlacaxipeualiztli. One might hazard the conjecture that in this case they took over the name of the Aztec month on account of its importance in fixing the year. The Quiche adopted no other Aztec name; the only other name adopted by the Cakchiquel was Izcal (Izcalli). The latter was specially important for the Aztec, being the first month according to the correlation of Alfonso Caso. So in each case it was only specially important month names which were borrowed. Apparently in the sixteenth century both Montezuma in Mexico and the Quiche and Cakchiquel in Guatemala fixed the true year by observing the equinox in the month Tlacaxipeualiztli, to which all gave the same name; and the practice, though not the name, has been continued to our own time by the Ixil, who have the same day names and dominical days as do the Quiche.

The question of correction by observation has exercised the minds of investigators for a very long time. To my mind this observation at Nebaj is very important indeed as it is the first evidence, except

the above from Motolinia, that such observations were really made. It is much to be desired that someone may check this at Nebaj before it is too late.

It is interesting to note the great advance of the Middle American calendars over that of the Hopi. The former were completely developed calendars by which any day in the past or future could be accurately fixed, an accuracy which the variable lunisolar calendars of the civilized nations of antiquity, not even that of the Greeks, had not reached. The ancient Egyptians are an exception, for they had attained that accuracy even though their year was a shifting one. Julius Caesar did the same and, fur-

thermore, removed the shift in his Roman calendar, founded on the Egyptian one. Nowhere else in the Old World had it been thought of, and the Greek astronomers had to use Egyptian years to obtain accurate computations. Yet the Maya had completed their calendar some centuries before the time of Julius Caesar. The Hopi, on the other hand, can fix dates for the year's work only by observation of the sun without any clear idea of a calendar. So much and no more accuracy was reached by the natives of Torres Strait (Haddon and Rivers 1901-1935), who could not count beyond two, yet could fix the time of year for work by observing certain stars.

PORTARLINGTON, IRELAND

Some Remarks on Maya Arithmetic

R.C.E. Long

J. Eric S. Thompson (1942) has set out very fully how the Maya might have used an abacus for calculating and he has given a diagram of such an abacus. Although I am in general agreement with his paper, I think that no abacus was used and that it is useful to consider the methods of reckoning used in Europe and very fully given by Francis P. S. Barnard (1916) with illustrative diagrams. He abstracts information given in ten arithmetical works of the sixteenth century. All give the method of calculation "by ciphers," that is, our ordinary arithmetical rules, but they also give the method of calculation by counters. The counters were called "jettons," and it will be convenient to use that term here. It was usual to have sets of jettons, which were made of silver or other metals, like coins or medals, and had ornamental designs, But as far as the theory of calculation is concerned, of course, any counters such as stones or grains of corn would do just as well. All the writers cited by Barnard consider the method by ciphers much superior to that by jettons. It was impossible to calculate "by ciphers" as long as the Roman numerals were used; the Arabic numerals came into general use only shortly before these works were written. One of the authors, Siliceus, who like Landa was a Spanish bishop of the sixteenth century, says "the reckoning by jettons is very useful to all persons deficient in a knowledge of written ciphering, as usually are merchants, money-changers, retail dealers, inn-keepers, and numerous others of low estate, besides such as through their own negligence or mental incapacity are unable to read, as is the case with many people of all conditions." It is a striking instance of culture change that the memory of such

reckoning has been quite lost in modern times and can be recovered only from the literature, for the practice was a commonplace in the sixteenth century. It is mentioned by Shakespeare and in many references to counting boards and to sets of jettons in inventories of property. When Landa said the Maya counted on the ground or on some flat surface he was referring to what was usual in Europe at the time he wrote.

No abacus was used. In some systems, like that of the English Exchequer, the reckoning was done on a cloth marked with vertical and horizontal lines like a chessboard. But this was not essential, and in several systems the counters were merely arranged in columns separated by spaces, that is, the columns were separated from each other by vertical spaces and within the column the different orders of units were separated by horizontal spaces. The system was decimal (except, of course, where special units, as of money, were required). In all the systems cited by Barnard, as also in the abacus, whether Roman, Hindu, or Chinese, the system was quinary-decimal, not pure decimal. Each decimal column is in two parts, the lower for units up to five, the upper for fives up to ten. When the addition of more jettons made the lower portion of the column amount to five, then five units were taken from this and one jetton added to the upper portion; when the upper part amounted to ten, then two jettons were taken from it and one was put in the lower portion of the next higher decimal column, and so on. So in the case of units with another radix, such as twelve; then the lower portion of the column was for units up to six, and the upper portion for sixes up to twelve. In practice this is much superior

to a purely decimal arrangement, as it requires fewer jettons and there is less chance of error in counting them. Thompson's abacus has only one column for each vigesimal order of units (as well as the special column for the 18 uinals of the tun). This is even more troublesome in a vigesimal than in a decimal system. It would be far more convenient to break up the columns into a quinary-vigesimal system having in the lower portions of the columns counters up to five and having in the upper portions counters for five up to twenty. I feel quite certain that this is what the Maya did. The tables of multiples in the Dresden Codex usually ascend by successive multiples of one up to five times, and then continue by multiples of five up to twenty; and of course the Maya numerals are on a quinary-vigesimal, not a pure vigesimal, system.

I quite agree with Thompson that only addition and subtraction were used. Here again the European systems are instructive. Most of them effect multiplication, where the multiplier does not exceed four, by multiplying the multiplicand by the multiplier, the latter being assumed to be known to the computer or to be taken from a table. But these works were written by persons familiar with ciphering. However, in at least three of the books cited, instead of this method the procedure is to multiply by putting down jettons for the multiplicand as many times as there are units in the multiplier. Thus, to multiply a number by three, the jettons for the number of the multiplicand are put on the board three times, and the result is then added up and put in the proper columns. Of course if the multiplier is ten, or any power of ten, then it is necessary only to shift the whole of the multiplicand so many columns to the left. Usually the books multiply by five by putting down jettons equivalent to half the number of the multiplicand and putting the result in the next lower quinary compartment, thus in effect multiplying by ten halves.

I do not think the Maya could multiply mentally or had multiplication tables, and it is evident that they could quite well proceed in this way by repeated additions. I have drawn attention to methods of multiplication because it seems to me often to be assumed that because the Maya used positional notation in their numerals they must therefore have been able to multiply and divide vigesimally as we do decimally. Probably they knew that it was possible to multiply by twenty or any power of twenty by shifting so many columns to the left, though even in this the tun column with its radix of 18 may have kept them from using vigesimal multiplication. I do not think they could multiply and divide freely by vigesimals, because the contemporary uneducated Europeans did not possess the knowledge of how to use their decimal system in this way.

I agree with Charles C. Fulton (Note 85) that the Maya system of positional notation is likely to be overstressed, and that it was in the main rather a sorry thing. Doubtless at first the zero symbol was inserted on the usual Maya principle of filling up blank spaces and without any conception of the potentialities of a positional system. One must note that on plates 46–50 of the Dresden Codex, where the four subdivisions of five synodic periods of Venus are set down, the last subdivision of each synodic period, which has the value of 8 kins, is written 0–8, which shows that the principle of positional notation was not really grasped. No doubt the zero was found useful to make clear what numbers were written, and the writing of numbers in the Codex was simplified by omitting the glyphs of the orders of units. In the Old World the Sumerians used positional notation with a radix of 60, and some Chinese coins had numerals with a radix of 10 (Couperie 1882), but it is not clear how far the principle was grasped in either of these cases. A somewhat similar situation arises in the case of alphabetic (as opposed to syllabic) writing. It is known that the ancient Egyptians used alphabetic signs as early as the first dynasty (ca. 3000 B.C.), but as Alan H. Gardiner (1943) says this was, as it were, accidental. They used consonantal signs for syllables which had only one consonant and one vowel, and ignored the vowel, thus expressing one consonant only. But such signs remained embedded in the writing which also contained many biconsonantal-syllables (read as two consonants only, again ignoring the vowel) and many ideograms; the writing so continued for over 3000 years without any improvement. The alphabetical principle was not really grasped then, nor was it understood by any people until probably 1000 to 1500 years after the first dynasty, when some Semitic people invented the first real alphabet. This had no vowels but neither had it any biconsonantal signs or ideograms.

Fulton says the Maya were the only people in the New World who used positional notation but he overlooks the Peruvian quipu, which had a decimal notation by position with a blank space for zero (Leland Locke 1923).

It should be noted that if an ancient Maya was adding up numbers which he had before him in a codex, he could quite well do so without putting down counters on the ground. He had merely to count up all the dots and put down the dots which remained after deducting all fives, and could then proceed to add the bars on the same principle by counting each bar as a five. I have often used this method myself in adding up numbers in the Dresden Codex.

PORTARLINGTON, IRELAND

Kaminaljuyu, Guatemala: Addenda and Corrienda

A. V. Kidder

In the recent report by Kidder, Jennings, and Shook (Kaminaljuyu, hereafter referred to as KJS) on the great archaeological site of Kaminaljuyu in the outskirts of Guatemala City, it was stated that four cultural phases were there represented: Miraflores, an Archaic or Middle Culture development; Esperanza, of the Early Classic Period; Amatle and Pamplona, which we assigned to the first part of the Late, or post-Classic, Period. We believed that in the terminal half of the Classic Period either Kaminaljuyu was not occupied or we had failed to hit upon remains which might have been laid down during that time.

Two years after the close of our field work, a local find suggested the presence of an additional early phase, but we did not have opportunity to study the specimens carefully enough to warrant its inclusion in our report. Still later, when the report was already in press, a discovery to Salvador made it evident that the postulated hiatus between Esperanza and Amatle-Pamplona had not existed and that the latter was, in reality, Late Classic. The new phase, which has been named Las Charcas, serves to lengthen the known occupancy of the site; the closing of the hiatus indicates that its occupancy was probably continuous.

Although these two pieces of information do not greatly alter our original conclusions as to Kaminaljuyu and its exterior contacts, they bear sufficiently upon certain wider problems of Mesoamerican prehistory to justify this postscript. The Las Charcas phase will be considered first:

Some 400 m south of the Esperanza mounds there is a slight rise in the generally flat terrain. This was chosen as the site of the Franklin Delano Roosevelt Hospital, a joint enterprise of the Guatemala and United States governments. We had previously examined the locality as part of our general surface survey of Kaminaljuyu, but had found no mounds and only a few sherds and chips of obsidian. When digging for the hospital's extensive foundations began in the spring of 1944, however, a small Esperanza tomb was encountered. The engineer then in charge, Mr. F. A. Crampton, reported it and kindly turned over to us the pottery and other objects it contained (KJS, p. 85). He was asked to save any further archaeological material that might come to light during the summer.

When I returned to Guatemala in the autumn, I found that Mr. Crampton had made a large collection of sherds from a series of bottle-shaped pits dug through the surface clay and into the underlying volcanic ash. The fragments were unweathered, with sharp, clean breaks, and it was obvious at a glance that they represented a ceramic complex not previously known. It was equally obvious that it bore some relationship to Miraflores because of certain close resemblances in vessel shapes and because very similar white ware occurred in both. On the other hand, there were lacking such characteristic Miraflores types as needle-point incised brown-black, heavily incised brown-black, and fine red. Several entirely unfamiliar types also appeared: red jars with bolster rim and simple incising, red-on-yellow bichrome

bowls, deeply scored graters. Detailed description of the Las Charcas wares will be included in a later report on the pottery of Kaminaljuyu.

The Crampton collection, of course, raised the question of the chronological relation of Las Charcas to Miraflores. This could not be denied on stylistic grounds, for the wares of the two groups were equally excellent.

For some time the specimens from the hospital were the only ones available for study. But in 1946 Shook found further sherds, thrown out in grading operations near Guarda Viejo, about 2 km east of the hospital. Again there were no mounds. A third find, once more unconnected with mounds, was made in the suburb of Santa Clara. In this case the sherds were picked up along a trench for a pipe line. Only in 1947 did evidence for the greater age of Las Charcas come to light.

In that year Shook examined a mound cut through by a road at Canchon, on the plateau some 15 km southeast of Guatemala City. Near its base was a burial accompanied by unmistakable 14 Miraflores vessels; in the fill were both Miraflores and Las Charcas sherds. As in the many rich Miraflores deposits at Kaminaljuyu, no Las Charcas had been identified, and as no Miraflores appeared in the hospital pits or in the lots from Guarda Viejo or Santa Clara, it was evident that the two ceramic complexes could not have been contemporaneous. Therefore, the occurrence of Las Charcas sherds in the Canchon mound, which was undoubtedly a Miraflores structure, indicated that Las Charcas was the older.

The Las Charcas phase is so far represented only by pottery. No mounds, no sculptures have been recognized. Clay figurines were perhaps made, as a considerable number were in the Crampton collection. But many of these differed from the sherds in being severely weathered and so may have come from the surface rather than the pits. Others were in better condition. Whether or not these can be distinguished from Miraflores types must await close comparative study of all such objects from Kaminaljuyu. None appeared at Guarda Viejo, Santa Clara, or in a most productive Las Charcas site discovered, by Shook, in the Department of Sacatepequez, some 20 km west of Guatemala City, where a road cut exposed a grave containing a number of fine vessels and a series of pits that yielded a large collection of sherds. This considerably extended the known range of the complex, until then confined to the Guatemala Valley and nearby Canchon, although a few pieces that are probably Las Charcas have come from a site at Calderas, on the south shore of Lake Amatitlan, and a single jar that has a suspiciously Las Charcas

look was ploughed up at San Rafael las Flores, 40 km southeast of Guatemala City.

The fact that Las Charcas wares, although older, are neither simpler nor structurally cruder than those of Miraflores renders still more puzzling the problem of Mesoamerican cultural origins. Their technical excellence argues for a long pottery-making background, of which to date no evidence whatever has come to light. This, incidentally, gives opportunity to correct my statement in the introduction to the KJS report that the precursors of the Andean high cultures had also eluded discovery. It was made before the Institute for Andean Research had worked out a series of developmental phases in the Viru Valley of coastal Peru extending back to a preceramic horizon. When detailed comparisons can be made, it will be interesting to see whether there are resemblances between what might be called the Middle Peruvian cultures and those of Mesoamerica, for a possible South American derivation of certain early Mesoamerican elements, the "Q-complex," has been suggested by Lothrop and Vaillant. Should local origins persistently fail to materialize, one would be forced to conclude that the ceramic art was introduced full-blown into Mesoamerica either from the south or from overseas. If from the south, some trace at least of its northward spread should exist. This highlights the urgent necessity of more intensive archaeological research in lower Central America and northwestern South America than has yet been undertaken.

To return to Kaminaljuyu, it is possible somewhat to amplify our earlier discussion of the Miraflores phase, because of a postwar building boom that has led to extensive destruction of mounds and in surface stripping to procure materials for bricks, tiles, and adobes. Of the resultant exposures, the most important has been that in the large mound at the municipal brickworks, which on the basis of sherds collected there in former years we considered to be a Miraflores structure (KJS, p. 241). This has been confirmed by the discovery, about 10 m down from the top, of a rich Miraflores tomb. Several other mounds that have been cut into have produced only Miraflores sherds, and great numbers of Miraflores refuse-filled pits have been encountered. Among the pottery thrown out from one of these, on the edge of the barranco east of the Verbena Cemetery, was found a fragment of what may have been a silhouetted relief sculpture (KJS, p. 102, Figs. 141, 142). As no Esperanza or Amatlé-Pamplona ware occurred at that spot, it seems possible that this type of carving, which we formerly believed too sophisticated to be assigned to so early a culture, actually dates from Miraflores times. It may be remembered that

an undoubted silhouetted relief fragment came to light in the Miraflores barranco, but as it lay at about the junction of the pure Miraflores deposit and an Amatlé-Pamplona stratum, we hesitated to date it (KJS, p. 103). Another surprising discovery was that of a "mushroom stone" in the abovementioned tomb (KJS, p. 142).

All in all, it is evident that the Miraflores culture was even more advanced than we originally supposed, so highly developed, indeed, that in spite of its carrying Usulután ware, elsewhere usually associated with early remains, and in spite of its finger-modeled figurines, one has the feeling either that it should not be classed as a Middle (Archaic) culture or that it had progressed more rapidly than its contemporaries. If the latter supposition be correct, Miraflores assumes considerable importance as perhaps having been a leader in development of planned mound groups, elaborate sculpture, jade carving (cf. Shook, Note 57), and other elements characteristic of the Classic Period.

A peculiar feature of Kaminaljuyu is the overwhelming preponderance of Miraflores sherds at practically every part of the site where digging has been done. That Kaminaljuyu was a less important center during the more poorly sherd-represented later phases does not seem probable because a number of its mounds are surely Esperanza; the very rich tombs at Mounds A and B argue for a highly prosperous community; and, though no Amatlé-Pamplona tombs have been found, several impressive earthworks can be assigned to that phase. This anomalous state of affairs might be explained by postulating that in Miraflores times Kaminaljuyu was a residential as well as a ceremonial center, whereas at a later date it became primarily ceremonial, the bulk of the population living more widely scattered about the valley and its environs. Still another possibility is that a great quantity of Miraflores pottery was ritually broken on certain occasions, as was done by the Aztec every 52 years (Vaillant 1940). Against this is the fact that the deposits bearing Miraflores pottery often seem to contain normal household rubbish, rather than quantities of freshly broken vessels, although some parts of the site do yield much material of that sort.

Also puzzling is the great rarity of common people's graves at Kaminaljuyu. One could account for the scarcity of Esperanza and the entire absence, so far, of Amatlé or Pamplona interments by supposing that the masses lived elsewhere. But, if the place was as densely inhabited as seems probable during the seemingly long Miraflores phase, thousands of burials should have taken place there and very many ought to have been encountered in the vast amount

of digging that has recently been done everywhere on the site, whereas the only ones certainly known are two that were found by O. G. Ricketson and myself at the Miraflores barranco in 1935. There is no evidence that cremation was practiced. Thus, one can only surmise that some single area, as yet undiscovered, was used as a cemetery.

We now pass to the closing of the supposed hiatus between Esperanza and Amatlé-Pamplona. When the report was written, Esperanza had been proved to be an Early Classic phase by the presence in its tombs of pottery, which, if not actually imported from Early Classic Petén sites, was unquestionably contemporaneous with them. Amatlé-Pamplona we believed to have been subsequent to Late Classic because it carried San Juan plumbate, a ware that so far has not been found in Late Classic Petén. And although we discovered no Amatlé-Pamplona metal at Kaminaljuyu, it had occurred at San Agustín Acasaguastlán on the Motagua in association with the early form of plumbate known as San Juan (Smith and Kidder 1943:173; in this publication San Juan plumbate is called "simple" or "non-effigy"). Metal was also unknown from Late Classic Petén, the only authenticated occurrence in any lowland Maya site of that period being a pair of gold figurine legs from beneath Stela A at Copán (Strömsvik 1941) and these might conceivably have been introduced at a later time. The lack, or at least the very great rarity, of Classic Maya metal strengthened our feeling that Amatlé-Pamplona must be post-Classic.

That we were wrong was indicated by finds at the ruins of Tazumal, in the outskirts of the town of Chalchuapa in eastern Salvador near the Guatemala border. There, Stanley H. Boggs (personal information) uncovered a group of graves containing both copper objects and pottery known as Copador, a type found in caches beneath Late Classic stelae at Copán (Strömsvik 1941). There was no San Juan plumbate in the graves, but there was a frog-pot and a miniature vessel, both of which practically duplicate specimens from Magdalena phase tombs at San Agustín Acasaguastlán, which also yielded San Juan plumbate and metal. Thus San Juan plumbate served to equate chronologically Amatlé-Pamplona with the Magdalena phase of San Agustín, metal to equate Magdalena with the Tazumal graves, Copador pottery to equate those graves with Late Classic Copán. Amatlé-Pamplona must therefore be considered Late Classic. By the same admittedly roundabout reasoning there is eliminated the formerly postulated hiatus between the Early Classic Late phase and the Magdalena phase at San Agustín (Smith and Kidder 1943:175), Magdalena, like Amatlé-Pamplona, now being assignable to Late Classic times.

The shoving back into the Late Classic Period of those cultures bearing San Juan plumbate bears significantly on the problem of the correlation of the Maya and Christian calendars. Under the Goodman-Martinez-Thompson, or 11.16, correlation, at present favored by most archaeologists, the close of the Classic Period, shortly after 10.3.0.0.0 in the Maya count, would have taken place at about A.D. 900, leaving somewhat more than 600 years to be accounted for between that date and the Spanish conquest. This is a long time, which Amatle-Pamplona, Magdalena, and other contemporaneous phases, originally believed to be post-Classic, helped to fill. Deprived of them, we are forced to stretch the at present known post-Classic phases almost to the breaking point. For this reason one cannot, as confidently as before, dismiss the possibility of an 11.3 correlation, which would end the Classic Period 256 years later, i.e. at about 1150. Such a correlation was, indeed, tentatively suggested by G. C. Vaillant (1927), who felt that there were not sufficient post-Classic remains to represent some six centuries or more of cultural activity. On the other hand, there is at the moment no way of estimating the length of such post-Classic phases as are now known, to say nothing of possible phases not as yet discovered.

In this connection it should be noted that R. E. Smith believes that each of the two Classic phases of Uaxactun, Tzakol and Tepeu, lasted for roughly three centuries. But in each of these he recognizes three subphases, which another student might have considered full phases. Vaillant, for example, working on the pottery of nearby Holmul, divided what there corresponded to the Early Classic Tzakol phase of Uaxactun into Holmul I-IV inclusive (Merwin and Vaillant 1932). About the same material from San Jose, British Honduras, is allocated to two phases, San Jose II and III, by Thompson (1939). This emphasizes the fact that phases, or numbered periods, or the foci of the Midwestern Classification, are products of individual judgment as to what constitute significant differences between one group and another of contemporaneous remains. Such divisions are no more than convenient preliminary classificational devices and, in the absence of reliable chronological landmarks such as Maya dates or dendrochronological determinations, should never be considered as measurable in years, nor thought of as having had anything like a standard duration.

If the present assignment of Amatle-Pamplona and the Magdalena of San Agustin to Late Classic is correct, there is rendered less convincing an argument which I formerly felt strongly to favor an 11.16 correlation. This was based on the chronology of Mesoamerican metallurgy and ran as follows:

Knowledge of metal-working came into Mesoamerica from South America. Since no metal had been found in Classic sites but was known from what were believed to be early post-Classic horizons, its introduction should have taken place not long after 900. This allowed time for metallurgy to have come to be practiced in Mexico by 1050 or 1100 and for copper bells to be traded to the United States Southwest, where they have been found in ruins of approximately those dates. But under an 11.3 correlation the Classic Period would have lasted until well after 1100, and it would obviously have been impossible for metal-working to have become established in Mexico as early as the Southwestern bells indicate. Now that we must believe that metal was already present in Salvador and Guatemala in Late Classic times, however, it is possible that even under an 11.3 correlation it may have become known in Mesoamerica early enough for the bells to have been brought to Arizona and New Mexico by 1100.

The above reasoning, if it can be so dignified, is based on the assumption that Mesoamerica owed its knowledge of metalworking to the south. It seems most probable that it did, but proof must await technological comparisons and chronological determinations both above and below the Isthmus. These studies are greatly needed. Without them we cannot be certain that there were not independent beginnings in Mexico or even, although I am far from being a Gladwinite, separate introductions from overseas.

To sum up, we can now recognize at Kaminaljuyu five successive phases; divisible into two groups: Las Charcas-Miraflores and Esperanza-Amatle-Pamplona. Between the first two there are many general resemblances and certain specific carryovers. The same is true of the last three. Between the two groups there are striking differences. In Esperanza new wares and new vessel shapes appear, accompanied by a marked decline in excellence of finish and in beauty and variety of forms, but with a distinct gain in the hardness and durability of the pottery that continues through Amatle and Pamplona. The strong resemblance of Amatle-Pamplona to Esperanza was hard to understand when it was believed that they were separated by the considerable stretch of time represented by the late Classic Period. The closing of this chronological gap removes that difficulty, but the break between Miraflores and Esperanza, discussed in the former report (KJS, p. 246), still remains unexplained. It must be remembered, however, that this unconformity is ceramic and that greater knowledge of other aspects of culture might result in a quite different grouping or, indeed, might indicate that the overall development had

been relatively uninterrupted. What little we know of Kaminaljuyu architecture illustrates these points, the greatest change coming not, as in pottery, at the beginning of Esperanza, but at some time during the life of that phase, when untterraced adobe substructures were superseded by terraced ones of tufa and clay with facings of pebbles and lime. As a matter of fact, this radical innovation appears to have been relatively short-lived, for perhaps before the end of Esperanza, and certainly by the beginning of Amatlé, adobe was again exclusively used. As to terracing we are ignorant.

I close with a correction which may or may not be of importance. The skeleton with pyrite-inlaid teeth that was informally interred during Esperanza times in the rubbish-filled excavation under the south edge of Mound B was stated to be that of a female (KJS, pp. 83, 217). Dr. T. Dale Stewart, however, has determined that the bones are those of a male. This being the only case of such dental ornamentation so far reported from the highlands of Guatemala, we surmised that the person so casually buried might have been a captive from some other area. If so, the sex of the individual might become a matter of some interest.

Did the Maya Have a Zero? The Meanings of Our Zero and the Maya "Zero" Symbols

Charles C. Fulton

Did the Maya have a zero? They had several symbols which have been translated by means of our zero, and the real question, naturally, is whether the translations are correct. Perhaps the answer might be either yes or no. Our symbol 0 represents several different concepts, according to the way it is used. The Maya also had at least two "zero" concepts, distinct if not entirely different, and represented by different symbols: these have both been translated "zero" or transliterated with our symbol 0. Spinden and other archaeologists have held that the Maya invented zero long before the Hindus, while at the same time saying that the Maya zero represents not "nothing" but completion.

To state my own view briefly at the outset, I believe our modern mathematical concepts of zero do embrace the Maya concepts; but I think that the most common idea of our zero is not at all equivalent to either "zero" of the Maya.

Ask anyone what our zero means, and he will probably answer that it means "nothing." This is indeed the pervading idea, and moreover a meaning that the symbol has had ever since its invention. Yet seldom does the symbol 0 or the word *zero* represent an absolute *nothingness*. Except in such cases as the formal contrast between *zero* and *infinity*, it is nearly always a very restricted kind of "nothing" or "no value" that is denoted by 0 or the word *zero*.

Our zero began about 1500 years ago as the representation of a mere blank space. It was just a meaningless cipher, used to hold the meaningful digits in their proper places, so as to represent the

whole number. Some people still think of zero in this way. In this sense it meant "nothing" or "no value" in a purely negative way; the symbol simply had no meaning at all by itself.

It was Stevinus who first held that in Arithmetic not unity, but zero, properly corresponds to the point in Geometry. From this has developed our most common modern concept of zero as the starting point of cardinal value. This is also a very restricted sort of "nothing"; just as a geometrical point has no dimensions but does have position. It should be noted carefully that this concept applies chiefly to our modern way of measuring continuous magnitudes. We do not begin with zero to number a file of soldiers; but we do begin with zero to measure lengths, times, and other quantities that we consider continuous or infinitely subdivisible. (Sometimes the zero is a purely conventional starting point of value, as for instance the 0 of the Fahrenheit thermometer.) This whole concept is fairly recent and I think it extremely unlikely that the Maya had any closely similar idea. This thought of zero as a *point* from which cardinal value takes its origin is, however, frequently read into the Maya symbols.

We have also a modern interpretation of the positional zero, no longer claiming that it means nothing at all as compared with the other digits. In the case of measurements, the symbol 0 may be a digit of measurement, representing the closest value for that place just as truly as any other digit does when so used. Some zeros may be used *merely* to fix the position of the decimal point and are not "significant";

the others are "significant figures" of measurement with the same status as any of the other digits. The Maya cannot have had this concept except we change from a cardinal to an ordinal point of view. This may be a good place to point out, however, that the Maya zeros were assuredly "significant." The Maya did not state any "round numbers" as approximations, but as dates to the exact day.

Our public also accept, though largely unconsciously, the concept of zero as a number of counting preceding one; that is, an ordinal zero. In such cases the 0 does not necessarily mean "nothing" in any sense. As a pure ordinal it indicates place solely, in the series 0, 1, 2, 3, etc.; but often some shade of the "nothing" meaning is subtly present, even when the usage is primarily ordinal. For example, in an examination a preliminary sample question, with answer given, may be numbered 0.

Modern mathematicians also use 0 (sometimes) as a cyclical ordinal. In this usage it may be substituted for the number of the cycle, or vice versa. When the count reaches the number of the cycle it simultaneously returns to zero again, and so on indefinitely. (This was explained, understandably I hope, in my recent "Elements of Maya Arithmetic," Note 85). There is here no essential connection with the idea of nothing, but if the cycle happens to be concerned with fluctuations of cardinal value, the cyclical zero may be taken to correspond with the zero of cardinal value. While it is of course true that in a cycle any element or point may be taken as a beginning, and likewise its repetition as an "end," one naturally as a general rule takes the cyclical zero as the cyclical 'turn' the end-and-beginning, the ordinal starting point or starting element which when repeated shows the completion or 'round' of one cycle of change.

Thus we have no less than six different concepts of zero in our own language, all distinct, and even, in extremes, quite different.

Let us now see what meanings attach to the Maya symbols translated by "zero," as nearly as the archaeologists have translated them for us.

Consider the "zero" day of the month, represented by the "spectacle glyph." It is *possible* to interpret this in terms of a zero signifying "nothing," "none," or "no," if we assume that the Maya were really counting nights, or that they were measuring the month in portions of duration from a zero starting point, and meant that no day had yet expired. (To me the latter idea seems far-fetched. For counting by nights in the Maya area see Thompson 1931, App. IV, quoting Herrera; Brinton 1885, "Annals of the Cakchiquels," quoting Sanchez y Leon; La Farge and Byers 1931, quoting the Ladinos.) J. Eric

S. Thompson thinks the "spectacle glyph" should be translated "the seating of." Why, anyhow, was it ever translated by our zero? Simply for this reason, and no other: that it designated the day preceding the day numbered one, with the same month name (cf. Bowditch). Thus the translation was in conception purely ordinal. Except that the other days carried numerals 1 to 19, I know of no evidence that the Maya thought of the 'spectacle glyph' as a numeral. If it is translated as a numeral, then logically and mathematically the numeral is 0; but the meaning is purely ordinal, and there is no connotation of "nothing" until we begin to interpret, as for instance by theorizing that the Maya counted only by "elapsed time" and meant that *no* day had *expired*. Perhaps it would be better not to use a numeral translation.

We have other evidence of the meaning. The same day could be designated either as the last day or completion of one month (using a different symbol from the "spectacle glyph") or as the beginning day or "the seating of" the next month. This designation of the same day as, in effect, either 20 or 0, even if the Maya did not actually intend their symbols to have a numerical value in either case, has all the aspects of cyclical counting. Certainly the Maya and their neighbors thought of time in terms of cycles, numerical cycles at that. The regular cycles of the months were, to be sure, interrupted each year by the five extra days. But these five days were considered entirely useless and probably were regarded as theoretically not part of the "true" or ideal year. The ideal year of 360 days has been a well-nigh worldwide idea, and is current even to the present time amongst the Hindus, whose "divine years," at least, have exactly 360 days, each day a year of mortals.

Let us now consider the positional zeros of the Long Count. Archaeological interpretation began with the showing that the Maya Long Count numbers, and other calendric numbers in the codices, could be translated into Hindu-Arabic numerals, and that like the latter the separate symbols (or groups of symbols in the Maya numbers) had position value, and included a "zero." It was most natural that this "zero" be interpreted in terms of the Hindu positional zero, that is, as the representation of a blank space, a symbol meaningless in itself, but giving meaning to the whole number by holding the other symbols in their proper places.

What then did the whole number mean? The Maya were counting completed days of duration as they expired, we are told. The Long Count is taken as the cardinal number of elapsed days from a zero starting point at some particular moment of the day 4 Ahau 8 Cumku. By this time another concept, based on *our* zero, has already wedged its way in,

zero as the starting point of cardinal value. Granting that this interpretation is possible, the question is, is it the true one?

May not another interpretation be more nearly correct? The cyclical counting in itself suggests an ordinal meaning for the "zero." The Maya were confirmed numerologists. When Katun 8 Ahau came again, the same powerful influences, the same god of the katun would rule as when Katun 8 Ahau had occurred previously. This idea in some degree applied to every day and to every number (see Colson 1926 for discussion of the Old World acceptance of our cycle of the week as a round of days ruled in turn by powerful influences.) The positional zero meant a return to some of the same influences that had ruled 4 Ahau 8 Cumku long ago, for whatever cycle the "zero" occurred in, whether of kins, uinals, tuns, or katuns. This is simply to say that the zero was a cyclical-ordinal; neither a cardinal "nothing" nor a blank in a cardinal number.

Outstanding archaeologists, authorities on the Maya, have insisted that the Maya zero represented completion rather than "nothing." I suggest we amend this to cyclical completion, which is the same as a new beginning.

If the counting begins at zero or its equivalent, then the round number dates are logically beginnings also. The date 9.0.0.0.0, for example, ought to be called the *beginning* of Baktun 9, especially if subsequent dates are said to be "in" Baktun 9, as is inconsistently done even at present when 9.0.0.0.0 is generally called the *end* of Baktun *nine*. That is, we should call the round number the beginning if we refer to a baktun as a period of duration at all. My own idea is that the Maya generally had reference to the round-number *dates*, katun *days*, etc., or to the *count* of a katun, etc.; not to a period of durational time. I doubt that they thought of their dates as being *in* baktuns or katuns. For that matter our own concept of centuries of duration is fairly modern.

How did the round-number dates, the days designated by zeros, come to be regarded as *ends* rather than beginnings? Spinden (1924) is especially emphatic about this, and in his case, at least, it almost seems that he has in mind that zero is not really a number. Thus he says, referring to the era of the Cakchiquels (*italics mine*):

"The count begins, as we have said, from a zero day, 11 Ah. The first *actual* day is, therefore, 12 Yix . . . The day Yix with numbers running from one to thirteen in a definite but peculiar sequence is the *initial* day of all the numerical positions or periods and the day Ah is *always last*."

In the case of the Maya it is possible to argue that the Zero Day 4 Ahau 8 Cumku is really the end of a preceding period; but how this argument can be applied to the era of the Cakchiquels escapes me. The quotation from Spinden clearly shows the sudden switch from a beginning zero day to a zero day which is "always last." Surely with our modern understanding of the number zero we would normally say that the zero day is the beginning day, and stick to it—whence it follows that the round-number dates are also beginning days. Cyclically, of course, the round-number dates and katun days can be *both* ends and beginnings; or *neither* ends *nor* beginnings, if regarded strictly as dates rather than parts of periods of duration.

To sum up: The translation of certain Maya symbols by our zero may be correct enough, provided we understand what concepts of zero properly apply. If we translate a symbol as "zero" because the meaning seems to fit one concept of our zero, we should be extremely wary lest we then apply some other meaning of our zero, which perhaps is not applicable to the Maya symbol at all. The Maya themselves probably did not read the "spectacle glyph" as a numeral. Its meaning is not too far from that of zero as an ordinal or a cyclical-ordinal; but if likely to be misunderstood, it would be better to translate with other words. As for the Maya positional zero, most archaeologists already hold that it is not identical with our zero. In my opinion it was primarily a cyclical-ordinal. If concepts derived from our zero intrude too much, it would be better to use some other symbol for it in transliterating Maya dates; for example, we might write 9.12.*.* instead of 9.12.0.0.0. Then the symbol could be taken to mean only what the evidence shows it to mean; or, at least, an explanation would not be encumbered with too many ideas derived from our own zero. It is very likely that too high a price is being paid for the convenience of translating by our familiar but too-little-understood word and symbol of many meanings.

WASHINGTON, D.C.

Jades from Guatemala

A. V. Kidder

In 1946 and 1947, A. L. Smith excavated two mounds at a large archaeological site in the outskirts of the town of Nebaj in the Department of El Quiche. The jades recovered are of much importance for the study of Mesoamerican ornaments of this material because of the fact that the age relative to each other of the tombs and caches in which they were found was determinable by stratigraphy; their cultural age, on the basis of the pottery they contained. Thus the jades, of which there were many fine carved specimens, can be assigned to three sequent periods: Early Classic, Late Classic, and the Postclassic horizon characterized by the presence of Tojil plumbate pottery.

Although large numbers of carved jades exist in collections, very few are accompanied by data as to age or provenience. Even fewer have been recovered in the course of controlled excavations. With the exception of the series from Monte Alban, not as yet fully published, that from Nebaj is the only one containing specimens to illustrate the types of jades in use at different periods over any considerable stretch of time.

Study of the Nebaj collection has resulted in recognition, among them, of certain categories of carved jades which, although they may be older, cannot be younger than the archaeological horizon in which they occurred. This in turn permits assigning minimum dates, in terms of cultural periods, to various pieces in museums and private collections as to which we had previously had no chronological information.

A number of the hitherto "floating," but now pretty certainly anchorable, jades are among those

91.1. Jades from Guatemala: (a) doubtful; length of c, 22 cm.

illustrated in the present Note. The cultural hook-ups of others are still uncertain. All are published, however, both because it is desirable that as much material as possible for the study of fades be made available and because the pieces shown in the first

91.2. Jades from Guatemala: (a) Late Classic; (b–d) doubtful; height of *e*, 14.3 cm.

five figures, being in a private collection in England, are not otherwise likely to become accessible. Furthermore, Mr. Smith and I wish to use a considerable number of them for comparative purposes in a report, now in preparation, on the excavations at Nebaj.

The period assignments here made will, for the time, have to be taken on faith. Our reasons for making them will be given in the above-mentioned report. The pieces shown in Figures 91.1–91.5 were found many years ago at unspecified sites in the western highlands. Those in Figure 91.6 are in the

91.3. Jades from Guatemala: (a, h) doubtful, possibly of Mexican origin. (scale in inches.)

91.4. Jades from Guatemala: all but *a* and *n* doubtful. (scale as in Fig. 91.3.)

91.5. Jades from Guatemala: (a) Late Classic; (b–h) doubtful (b, e, h, and i are probably not jade; I have not seen any of these specimens); (i) Olmec (?) or perhaps Olmec-influenced; (j) Late Classic (?); (k) doubtful. (Scale as in Figs. 91.3 and 91.4.)

Museum of the American Indian, Heye Foundation, and are reproduced with the kind permission of Mr. George G. Heye. They are thought to have come from the vicinity of Mazatenango, on the Pacific slope in the Department of Suchitepequez. All of both lots are tentatively identified as Early Classic, except as noted below.

91.6. Jades from Guatemala: (h) doubtful; height of *b*, 11.2 cm; of *d*, 10.5 cm.

Certain Archaeological Specimens from Guatemala I

A. V. Kidder

Most of the objects treated in this Note were incidental finds or purchases made in the course of Carnegie Institution's field work. As such, they will not find a place in papers devoted to major excavations and surveys. The rest are in private collections which are unlikely ever to be published and always risk loss or dispersal. Some of the specimens are well documented. The exact provenience or the cultural affinity of others is doubtful, but among these are pieces that throw light on technological processes or provide well-preserved examples of types hitherto known only in fragmentary condition. It therefore seems worth while to put them also on record. Unless otherwise stated, all are now in the National Museum of Guatemala.

Pyrite-incrusted plaque. From an Esperanza Phase (i.e. Early Classic) tomb at Kaminaljuyu there was recovered, in 1928, a plaque whose back was coated with stucco and elaborately painted (Kidder, Jennings, and Shook 1946, Fig. 175a). Its decoration, remarkable both for an apparently unique method of application and for unmistakable Teotihuacan affinities, is described in the same publication (1946:130, 234). It was found lying face down and as it was obviously in shockingly rotted condition it was removed to the laboratory in a lump of earth cut from the tomb floor. The face thus remained hidden while the decoration of the back was being reproduced by Sr. Tejeda in watercolor. It was planned, indeed, to keep the specimen as excavated, in order to save the painted surface intact for museum display. But in

spite of the application of preservatives the underlying slate continued to crumble to such an extent that the decoration was destroyed. In 1948 it was therefore decided to remove the disintegrated backing and examine the face. This was done by carefully brushing, with the interesting result shown by the accompanying photograph (Fig. 92.1a).

The central element of the face proved to be a 12 cm slate disc 6 mm thick. This had been covered with a mosaic of polygonal plates of pyrite, which had become completely altered to a yellow crust. The small interlocking elements, probably 14, that surround the disc, and the petal-like outer elements, probably 12, were of stone, their curving edges accurately cut for close fit. They bore a thin yellow coat of altered pyrite, the remains of a layer of that mineral naturally deposited on the stone matrix.

A second plaque, likewise faced with a central disc surrounded by curving matrix-and-pyrite "petals," was found at Kaminaljuyu (Kidder, Jennings, and Shook 1946, Fig. 155h; the drawing of this plaque, Fig. 53d, is faulty in showing six rather than seven "petals" and in indicating that they were set with pyrite polygons). Still another from the same group of tombs has a central disc ringed with matrix-and-pyrite cutouts that may represent bird heads (Kidder, Jennings, and Shook 1947, Figs. 53b; 155i).

Matrix-and-pyrite was also used at Kaminaljuyu for the polygonal elements of the incrustation of a few plaques. More commonly, the Kaminaljuyu plaques were incrustated with polygons cut from pyrite crystals. Matrix-and-pyrite incrustation has been found

92.1. Archaeological specimens from Guatemala.

at Nebaj, Department of El Quiche, but there too it is less common than incrustation of pure pyrite. The two materials apparently were never mixed in the same area of incrustation, although they might be used, as in the case of the present specimen, on different parts of the same plaque. There is no record of the use of matrix-and-pyrite on plaques from lower Central America, nor on those from Alta Verapaz. It is reported, however, from Iguala, Guerrero, as polygons on plaques (Saville 1922:52) and there are single-piece plaques, also from Iguala, in the Museum of the American Indian; several single-piece examples in the National Museum of Mexico are from Michoacan. Ekholm (1945) describes a single-piece matrix-and-pyrite plaque with carved back. It is said to be from Queretaro. In the museum at Morelia, Michoacan, are several necklaces of neatly and variously shaped matrix and pyrite elements. Kelly (1947) found at Apatzingan, Michoacan, one-piece

matrix-and-pyrite plaques but, with the exception of a single pyrite polygon, no evidence of incrustation. She also recovered many matrix-and-pyrite elements that evidently had been combined with elements of shell to form necklaces or ornamental bands. Their cutting was accurately done, in some cases in such a way that the pieces interlocked. This of course suggests the close fitting of the "petals" and the interlocking of the inner ring of the Kaminaljuyu specimens. The Apatzingan material is of the Delicias Phase, believed by Kelly probably to equate chronologically with Teotihuacan III. In view of these more abundant northern finds, and because of the undoubtedly Teotihuacan III style of the Kaminaljuyu plaque's painted back, it is possible that all the Guatemala specimens on which matrix-and-pyrite was used were importations from Mexico.

Tool for reaming earplug flares (Fig. 92.1b), a surface find by A. L. Smith at Chalchitan, a large mound group near the town of Aguacatan, Huehuetenango. It is a lump of fine-grained but gritty sandstone, 14.5 cm long. One end has been worked to a point, round in section at the base and showing long wear. It is of exactly the proper size and shape for reaming out the face and throat of a jade earplug flare. The originally rough edges of the rest of the specimen are softened and smoothed by protracted use. The side that appears in the photograph bears a shallow longitudinal trough, doubtless used as an abrading surface, probably for the preliminary shaping of jade objects. A very similar specimen is from an Esperanza Phase mound at Kaminaljuyu (Kidder, Jennings, and Shook 1946, Fig. 154a). The length of occupancy of Chalchitan is uncertain. Sherds collected there by Smith indicate that it was in existence during Early Classic times; Postclassic Tojil plumbate ware is also present, but the site had certainly been abandoned well before the conquest, for no protohistoric pottery types occur.

Cache of small ornaments (Fig. 92.2c-o; all specimens in this figure natural size). Found lying together in a hole anciently cut through an adobe floor beneath a small mound immediately south of Mound B, Kaminaljuyu. They came to light during grading operations in connection with the building of the Franklin Delano Roosevelt Hospital. Their age is uncertain but I believe them to date from the Amatlé-Pamplona Phase (i.e. Late Classic). In both material and form they are unlike anything from the Esperanza Phase (i.e. Early Classic) tombs of Mounds A and B. Notes: Figure 92.2m: Dark red stone, salient parts of front and whole back highly polished; conical hole on right of forehead slants inward to meet second

similar hole drilled straight in from back; left side probably treated in same way, but edge broken off a considerable time before specimen was buried, as fractured surface shows much wear. Pairs of biconical holes through chin. Fig. 92.2n: Same stone, same sort of perforations. Fig. 92.2o: Dark green stone (not jade), low polish; biconical holes, Fig. 92.2c, e, f, i, l. Same red stone as Fig. 92.2m; well-polished, cylindrical perforations; three other specimens like Fig. 92.2f not figured. Fig. 92.2g, h, j, k: Deep black stone, high polish, cylindrical perforations; two other specimens like Fig. 92.2m, n; Fig. 92.2k, broken edge much worn, as in m. Private collection.

Pendant (Fig. 92.2a). Dark gray stone, highly polished, biconical suspension hole drilled from front; surface find, Kaminaljuyu. Private collection.

Parrot (?) head (Fig. 92.2b). Gray-green jade, well polished; both sides bear same carving; cylindrical perforation in long axis passes through mouth-cut; latter a good example of string-sawing, started from cylindrically drilled hole at back of cut. Said to be from Kaminaljuyu. Private collection.

Small bird head from La Brigada, Department of Guatemala (Fig. 92.5b). Surface find. Dark red stone similar to that of some of the small objects shown in Figure 92.2. Eyes and nostrils made with conical drill, biconical perforation. Length 3 cm.

Stone human heads (Fig. 92.8j, k). Purchased at Rabinal, Baja Verapaz. Light green crystalline stone, gray patina. Larger head (Fig. 92.8j) a complete object, i.e., not broken from a figurine. On either side of back at eye level a pair of conical drillings that meet at right angles to provide attachments for suspension string. The smaller head also probably a complete object, but has no attachment holes. Both in material and in rendering of faces, these specimens are unique. Length of j, 13.5 cm.

Textile-marked sherds. The specimens described below add to our unfortunately very scanty knowledge of ancient Mesoamerican weaving. Certain of them also indicate a peculiar use of textiles in pottery making that has, I believe, not previously been noted.

1. Finca Variedades, near Guatalon, Suchitepequez, collected by E. M. Shook at a site with much broken pottery and fragments of manos and metates, but no mounds. Six sherds (five shown in Fig. 92.3, scale about X 1.5; plasticine casts to the left). All are from flat, unslipped utensils, presumably comales

92.2. Archaeological specimens from Guatemala.

(tortilla griddles) of reddish brown clay sparsely sprinkled with tiny flecks of yellow mica. One side of each is evenly smoothed, the textile-marked surface slightly undulating (Fig. 92.3a). I think this was probably due to a cloth having been spread on imperfectly smoothed ground and the clay pressed down on it. In Salvador, comales are made today in shallow, dish-shaped hollows scooped into hard earth, a dusting of wood ashes serving to keep the clay from sticking. The only rim sherd (Fig. 92.5a; textile print on lower surface; specimen not photographed because print indistinct) indicates a diameter of about 50 cm. All but one of the textiles were of plain weave. The clearest print (Fig. 92.3e) is of a piece of "open" fabric, i.e. one with relatively large spaces between both warps and wefts. The yarns, about 0.3 mm in diameter, were evidently hard, as they have left deep, sharp impressions. There was none of the crepiness noted by Dr. O'Neale in textile prints from Kaminaljuyu (Kidder, Jennings, and Shook 1946:98; see also Fig. 170a, b, which shows similar crepy fabrics from Peru). The yarn count is 8 or 9 per square cm each way, the interspaces about 1

92.3. Archaeological specimens from Guatemala.

mm square. Another print is similar (Fig. 92.3b; yarn count 7 by 7, threads somewhat softer and heavier). A third (Fig. 92.3.1) is more open, the interspaces about 1.5 mm square. It is the one, just mentioned, in which there is a variation in the weave. Most of the fabric is plain, but at the right the wefts pass alternately over and under a single pair of warps. If this, as seems probable, was done at regular intervals throughout the piece a striped effect would have been produced. In two other sherds (Fig. 92.3c, e) the wefts are double; each consisting of two yarns laid in side by side. The weave of c is close. The count is again about 7 by 7, but both warps and wefts were softer and "fatter" and have left no interspaces. At the middle of e, single warps apparently alternate with the doubles for a space of four or five picks. If, as seems probable, the singles were of contrasting color, striping would again have resulted.

2. Zaculeu, Huehuetenango. Four sherds (Fig. 92.4b-e, scale about X 1.3; casts to the right). These

are from a small, low mound south of the narrow, deep little valley that forms the southern boundary of the main Zaculeu site. A. L. Smith excavated the mound in 1945, recovering some 2,000 fragments of small moldmade and larger hand-modeled human figurines, the latter with moldmade heads. All are much weathered, as if they had lain long on the surface before being buried. The same is true of the four textile-marked and a few other sherds, among which are two of Tojil plumbate, indicating that the mound was erected in Postclassic times. The textile-marked pieces are of dark brown, unslipped ware without mica flecks. The textile prints are on the concave surface of three of the pieces; the fourth bears the print of the same sort of textile on both sides (Fig. 92.4e, convex surface shown): None has a finished edge. Whether they are parts of small jars or of the larger type of figurine is uncertain. The textile used on two of them (Fig. 92.4b, c) was a plain open weave of hard yarns, their impressions, like those of all but

92.4. Archaeological specimens from Guatemala.

one of the Finca Variedades specimens, being clear and sharp. The count is 11 by 11, the yarns a little less than 0.5 mm in diameter, the interspaces slightly over 1 mm. Another piece (Fig. 92.4d) shows double warps and triple wefts, the yarns in each case laid side by side. They were thicker and softer than the open-weave yarns. The count is 5 by 5. The sherd at a shows double warps and wefts in a more open weave, 4 warps and 6 wefts.

3. Cahyup and Chuitinamit near Rabinal, Baja Verapaz, are Late Postclassic sites at which A. L. Smith collected sherds in 1947 (Smith, 1947:184). Among them are a number of pieces from the lower parts of coarse black jars, each bearing textile impressions on the concave inner surface (Fig. 92.4a, f, g, a from Chuitinamit, f, g, from Cahyup; scale about X 1.6). The cloth was a plain open weave of hard single strands, the count about 10 by 10. What purpose the textile served in the making of the lower part of these vessels, is a mystery. It seems either to have covered a convex mold or a rounded anvil such as was used in the paddle-and-anvil method of pottery making, but in the latter case one would expect to find the impressions crisscrossing over each other, whereas on all but one sherd they are sharp and clear, as in 92.4a and 92.4g. Only in Fig. 92.4f is what appears to be a double impression and this looks to have resulted from the use of two layers of textile, rather than from two applications of an anvil. A mold seems indicated, but why cover it with cloth? Only the lower half of the vessel was treated in this way, the upper half having been built up in normal fashion (see Fig. 92.5d, drawn from Fig. 92.4e, which is inverted in the photograph, the lower part showing the thickening caused by the overlapping of the prepared base, drawn in black in Fig. 92.5l by the lower edge of the pot's upper wall). During the building of the upper wall, or perhaps in removing the presumably moldmade base from the mold, the textile impressions were in places obliterated (see Fig. 92.4f, g). And in the sherd at a the entire interior of the pot's lower body was covered with a 4 mm layer of clay, which has split off at the edges showing the underlying textile impression.

Pottery from El Cerrito, Department of Santa Rosa. Four purchased vessels, said by a reliable person to have been found by himself lying together in one of the several mounds in the town, which is some 25 km southeast of Chiquimulilla. The jade illustrated in Figure 92.8h is stated to have been with the vessels.

1. Pseudo-gadrooned vessel (Fig. 92.6a) black, exterior well polished, prepolish groove-incised

lines producing gadrooned effect run to edge of slightly recurved base. Height 14.5 cm.

2. Lobed vessel (Fig. 92.6b). Brownish-clouded black, exterior indifferently polished, four evenly spaced vertical prepolish groove-incised lines and similar lines about "waists" between two upper lobes. False bottom, its edge forming low ring-stand, contains several pebble (?) rattles; four round 5 mm vents in wall of false bottom, single 4 mm round vent in middle of bottom. Height 19.5 cm.

3. Monkey (?) pitcher, front and side views (Fig. 92.6c). Dark brown, poorly finished, marks of polishing stone obvious; arms, sex organs, bosses on neck are smoothed-down fillets and lumps; base rounded; handle cylindrical in section.

4. Polychrome cylinder (Fig. 92.6d). Originally well-finished surface badly eroded. Plano-relief braided design in two opposed panels, the relief painted black. Painted decoration in red, orange, and black on yellowish slip; almost obliterated but appears to have consisted of three human figures on one side, four on the other. Encircling vessel just below rim and just above base are close-set, conventional human faces (Fig. 92.5c). Upper 14 cm of interior also decorated with repeated units, nature uncertain. About edge of slightly recurved bottom a series of interlocking "lazy" S's. Height 23 cm, diameter of base 17 cm.

In spite of its bad condition, this vessel has been described at length because it is the only specimen of its sort which, as far as I know, has come to light in Guatemala. It is of the Honduran Ulua-Yojoa type (cf. Strong, Kidder, and Paul, 1938, Pl. 8). The monkey (?) pitcher also has eastern affinities, there being similarly shaped examples, likewise phallic, from Asuncion Mita, Department of Jutiapa, and from western Salvador. It would appear that southeastern Guatemala, about whose archaeology almost nothing is known, formed part of a ceramic area embracing the Ulua-Yojoa country and western Salvador, the latter region also producing polychromes of Ulua-Yojoa type.

Effigy vessel (Fig. 92.6e). Purchased in Guatemala City, said to have come from Department of El Quiché; E. M. Shook believes, however, that it may be from Salcaja, Department of Quetzaltenango (personal information). It seems surely to be of Archaic (Middle Culture) date, because of its double-punch eyes and its soft, brownish black, well-polished ware, much like Miraflores brown-black. Strong, Kidder, and Paul (1938, Pl. 15a) illustrate a spouted effigy of almost identical form, but without incising, from an early (Playa de los Muertos Bichrome) horizon at Lake Yojoa, Honduras. The incising and

92.5. Archaeological specimens from Guatemala.

punctuation of the present specimen is prepolish. Total length 20.5 cm.

Moldmade adornos from Kaminaljuyu (Fig. 92.6f-h). These are of interest because of the rarity of Middle American examples of casting from vegetal forms. The specimens are fragments of large, ornate incense burners of coarse reddish brown ware, unslipped, but bearing traces of thin white paint. All three are from Amatlé-Pamplona, i.e. Late Classic, deposits: 92.6f, a nubbly fruit or vegetable, and 92.6h, are from a stratum overlying the Esperanza Phase, i.e. Early Classic, frontal platform of Mound A; from near Mound E-III-3, in a deposit containing

many fragments of incense burners and large, hollow clay figurines. Length of vegetable in f, 6 cm, of ear of maize in g, 8 cm, of part of ear in h, 6 cm. The broken edge of the latter shows it to have been cast separately and welded to the vessel, as doubtless were the other two.

Hollow figurine from Kaminaljuyu (Fig. 92.7a). Purchased at the site. The vendor said that her husband, hearing the rattling of what, from the size of the vent, must have been a large pellet, now lost, broke off the head in search of treasure. The figurine is of coarse brown ware, covered by highly polished

92.6. Archaeological specimens from Guatemala.

red slip 1 mm thick, now largely flaked off. There are traces of a string of oval beads that had once extended around the front of the neck from earplug to earplug. Height 38.5 cm. This is without question a Miraflores, i.e. Archaic, figurine, the double-groove-and-central-punch eye and the thick, polished red slip being characteristic of that phase. Few Miraflores figurines, however, are hollow and complete

specimens are very rare, I have, indeed, wondered about the fragmentary and battered condition of most figurines from Archaic sites in Guatemala and elsewhere. Could it be that, like the Hopi kachinas, they had brief service in ceremonies and were then given to the children as playthings?

Figurine leg from Kaminaljuyu (Fig. 92.5e). Found by E. M. Shook in a Miraflores deposit ex-

a

a'

a''

b

b'

92.7. Archaeological specimens from Guatemala.

92.8. Archaeological specimens from Guatemala.

posed in a road-cut. Typical yellowish white, finely finished Miraflores ware. It offers the first evidence that jointed figurines were made by Archaic people, the only other examples hitherto known being those from Teotihuacan, which are of Early Classic (Teotihuacan II or III) date. The latter specimens differ from this in that the tops of the legs were perforated and a string was run through them and through a transverse hole in the pointed lower part of the body. In the present case, it would seem that each leg must have been separately attached, its perforated boss having fitted into a cup in the edge of a flattish body that was perforated front-to-back. Length 7.5 cm.

Pottery mold (Fig. 92.7b; at right a plaster cast from same). Believed to be from Alta Verapaz. Lower arms and hands evidently meant to be added after casting. Height 25 cm. Mold in private collection, Guatemala; cast in Peabody Museum, Harvard.

Polychrome jar (Fig. 92.8i). Purchased in Guatemala City, provenience unknown. Neck red, body slip cream with decoration in black-bordered red, six bird (?) heads (Fig. 92.5f) on upper body, six N-shaped figures on lower body. Strap-handles, width

2.5 cm. Base recurved. Height 20 cm. I believe this to be a protohistoric or early colonial piece. Polychrome, two-handled jars with red necks were found at Zacualpa by Wauchope (1948, Figs. 73, 74), who assigns them to the late Yaqui Phase; they contained cremations. Said to be from Zacualpa is a similar jar (Lothrop 1933, Fig. 30); and there is one from Chuitinamit, Atitlan, the 16th-century Zutugil capital (Lothrop 1936, Fig. 59k). There is, incidentally, the greatest need of information as to conquest and early colonial wares, to serve as a datum from which to work backward. Private collection.

Small carvings from western highlands (Fig. 92.8a–g). Exact provenience unknown. Most of these specimens, which I have not seen, are apparently of jade; c appears to be of black stone. Height of b, 5 cm. Private collection in England. Other pieces in the same collection are illustrated in Note 91.

Jade from El Cerrito, Department of Santa Rosa (Fig. 92.8h). Said to have been found with the pottery vessels shown in Figure 92.6a–d. Very fine, deep green jade, high polish front and back, transverse bi-conical perforation at eye level. Height 6.7 cm. Private collection.

Some New Discoveries at Coba

William R. Coe and Michael D. Coe

In December 1948, we made a trip to Coba for the purpose of photographing the ruins. Starting from Valladolid, we went to Chemax, thence on mule back to Tsinup, approximately 12 km beyond. About halfway between Chemax and Tsinup we observed, across a milpa to the right of the trail, some rather large and well-preserved buildings, which appeared to be on an acropolis. Leaving Tsinup at six o'clock in the morning, we traveled the 20 km to Coba over a very bad trail in about seven hours, and made camp on the shore of Lake Macanxoc.

The destination of Sacbe No. 15 has been the source of some speculation. J. Eric Thompson thought that it might run to Ixil (Thompson, Pollock, and Charlot, 1932:27). Sidman P. Poole states, on the authority of a guide, that it probably continues all the way to Guatemala (*Geog. Jour.*, 95:124). Actually, after starting out between Lakes Coba and Macanxoc at an angle of 199° (all compass directions are read from N. to E), it crosses Sacbe No. 16 and terminates at a group of ruins approximately 3.5 km from the intersection. It is perfectly straight throughout, and is in excellent condition. The group at the terminus we named "Uxulil Be," or "end of the road" (Fig. 93.2). Two new sacbes were found branching out from No. 15. The first, Sacbe No. 17, leaves No. 15 about 1 km south of the intersection of Nos. 15 and 16 in a direction of 120°. It continues for 107 m and ends at a small group of ruins which we named "Pech Mul," meaning "tick mound." The second sacbe, No. 18, branches out in the opposite direction about 2 km south of the main intersection, and con-

tinues on a course of 300° to an unknown destination. Along Sacbe No. 15 were observed many small mounds in very bad condition, but their exact location was not noted.

Uxulil Be (Fig. 93.3) consists of a large structure and some smaller mounds lying on a raised rectangular terrace of considerable size. The main building, Structure I; is oriented to 19°. It rises in a series of three terraces, the stairways to each being aligned with the terminus of Sacbe No. 15. Flanking mounds extend from Terraces C and D. The three mounds on the highest terrace, D, are in complete ruin and are so low that the only type of construction possible would have been base-walls with thatch roofs. The masonry of each terrace facing is of a rather good quality for Coba (Fig. 93.1a). The total elevation of Structure I is 15.2 m. Two mounds are placed on either side of the main terrace, A, near its northern end, and a tiny square mound sits on the northwestern corner.

Pech Mul lies on a terrace of two heights (Fig. 93.4a, b), of which only A was mapped, as there are no ruins on the lower terrace. Structure I, oriented to 3000, is a small pyramid with a single stairway (Fig. 93.1b). The stairway is badly ruined, but, from the few steps still in place, was evidently much wider at the bottom than at the top. On the summit of Structure I is a large and very curious room, with only the walls standing. Its dimensions suggest that it was once divided into smaller rooms, but only two interior mounds (Fig. 93.4a, b) remain, differing considerably in length. If these were the dividing walls,

*a**b**c**d*

93.1. Coba: (a) Uxulil Be, facing of Terrace B on left of Stairway 1; (b) Pech Mul, northern corner of Structure I, stairway on right of photograph; (c) Pech Mul, northeast wall of room on summit of Structure I, showing spring line and Mound A (at right); (d) Pech Mul, small altar or shrine on summit of Structure I.

the rooms were highly asymmetrical. The absence of fallen stone between these mounds and the front and back walls implies that no vaults had existed. Nevertheless, a spring line was found about 2.1 m high on the northeastern wall, formed by a row of slabs (Fig. 93.1c). Possibly there had been a beam-and-mortar roof supported by a small corbel. At the back wall is a low bench (Fig. 93.4d), its extent undetermined because no excavations were made. At the front of the room, just behind the doorway, is a small, square, masonry structure with a lower projection (Fig. 93.1d), probably a shrine or an altar, indicated by the presence, at the top, of flat stones caved in at the center. Structures II and III on Terrace A are ruined mounds. The purpose of Structure IV, a circular ring of masonry about 0.3 m high, is unknown.

Another new *sacbe*, No. 19, was found at Nahoch Mul but not followed. It starts off in a northeasterly

direction from a group of mounds situated about 12 m from the northeast corner of Structure I.

An interesting change of name was noted from the information of our Indian guide. The southeastern most lake at Coba is named "Sacakal" on the Carnegie Institution map of the site. The guide, who has hunted all his life around Coba, said that its real name is "Sacal Puc." Sacakal, "reed-covered swampy depression," is a purely descriptive name; Sacal Puc is the name of the greatest of the Maya lineage gods; he was one of the first four Mexican conquerors of Yucatan and founded many settlements in the eastern part of the peninsula. Scholes and Roys (1938:609), in speaking of Sacal Puc, say, "Indeed, he still figures in the Maya prayers of modern *yerbateros* as the first man to offer *posole* to the Chacs." There is a thorough discussion of Sacal Puc in Tozzer (1941:9, 34).

93.2. Location of the sacbés.

93.3. Plan and elevation of Uxulil Be.

93.4. Plan and elevation of Pech Mul.

Measurements in this paper are approximate; orientations were obtained with a simple but reliable pocket compass.

Editor's Note

I wish to call attention to the fact that the greater part of the material in Note 93, "Some New Discoveries at Coba," had been recorded previously by E. Wyllys Andrews (1938), who visited those outlying groups in 1937 and subsequently published his observations.

For the authors, young students at the time little acquainted with the Maya area, ignorance of Andrews' paper, published in a foreign journal, is understandable; on myself, as editor of the "Notes," must fall the full blame for the mistake. I have no excuses to offer; I tender my apologies to Dr. Andrews for my negligence. Not Jove, but a Ganymede, no competitor of Juno, nodded.

Note 93, however, serves to supplement Andrews' paper, for it gives fuller details of the plaza at which Sacbe 17 terminates, and establishes that the sacbe ends against the center of the plaza, not on the south edge (at the time of Andrews' visit the plaza was deep in *guamil*). Moreover, to the Brothers Coe are due the discoveries of Sacbes 18 and 19.

J. ERIC S. THOMPSON

Tlaloc Incensarios in the Baratta Collection, El Salvador

Stanley H. Boggs

The collection of prehistoric pottery vessels owned by Prof. Augusto and Doña Maria Baratta of San Salvador, El Salvador, includes many fine specimens, most of which, unfortunately, are of unknown provenience. The five incensarios with which this paper deals were purchased by Doña Maria in 1944 from a workman who stated that they had been discovered on the Hacienda Chanmico, property of Don Alfonso Quiñonez. This farm lies immediately south of the Hacienda Sitio del Niño and is geographically at least within the San Andres Archaeological Zone, in sight of the mounds forming the Sitio del Niño group of that zone. However, no ancient structures have been reported on the Hacienda Chanmico itself.

The Baratta incensarios are reported to have been uncovered a short distance below the surface of fairly flat land, placed to mark the four corners of a square oriented to the cardinal points, with one vessel at each corner and the fifth in the center. An urn containing human bones is said to have appeared a short distance under the central incensario but this was not available for examination.

How much of this arrangement may be accepted as fact is impossible to prove since similar finds are so far unknown. Furthermore, in El Salvador at least, sales of ancient objects are almost invariably accompanied by what the seller considers a good story in order to endow his merchandise with greater value. Such stories are infrequently true, occasionally amusing, and generally fantastic.

SPECIMENS

The five vessels are so similar, one to the other, that all will be described together as to fundamental features.

Form: Essentially hourglass shape. Decorative details, applied exclusively to bands around the top, bottom, and one side of the exterior, do not basically affect this form. The interior of four examples (Vessels 1, 2, 3, and 5) show division into an upper (or container) vase portion, and a lower, very high annular-base support. Bottoms of the container sections are flat and were formed in two distinct ways: (1) true bottom, shaped by clay added to and thinned inward from the side walls, one small round hole was punctured in the center of this bottom; (2) removable bottom, consisting of a disc-shaped, re-used sherd. This disc rested on a narrow flange which extended inward a few centimeters from the side walls. The interior flange was shaped at the same time as the incensario itself (Vessel 5, Fig. 94.3b) or a large hole was cut through an original true bottom (Vessels 2 and 3). Vessel 4 has no bottom; in case a removable disc was originally employed for this purpose it must have been supported simply by the constricted side walls of the vessel's middle height (Fig. 94.3a).

Rims, both superior and inferior, were thickened and flat, or slightly concave. All specimens show small round holes, one to each side, punctured into the basal portion of the vessel just behind the vertical flanges which divide the decorated from the undecorated halves.

Surface: Unpolished. All specimens show signs of having been hand-smoothed and patted. Horizontal striations are apparent on all vessels and especially noticeable on the basal and undecorated areas. These striations are usually very regular and suggest use of flat sticks or possibly stones in smoothing of the surface. Interior surfaces also show indentations due to pressing of the moist clay with the fingers.

The surfaces are generally granular, and are uneven to the touch except for the horizontal ridges encircling the basal and rim areas: these are so regular that one is reminded of the marks on wheel-made vessels.

Clay: Various shades of red-brown. Rather coarse texture. Much pumice and mica temper. Apparently even firing.

Decoration: Mainly modeled, some incising and some painting. In all specimens, confined to one half of the exterior surface, plus rim and base bands.

The principal decorative motif of all five vessels consists of a partially squatting, rather grotesque figure in full face, the legs and head of which are modeled in the round and the remainder of the body in bas-relief; the entire figure applied to the exterior surface of the vessel and framed above and below by horizontal bands of concave discs and, at the sides, by short vertical flanges. The face of the dominating figure is characterized by features generally considered attributes of the god Tlaloc. The right arm of this figure generally slopes downward from the shoulder but the right hand is turned up, palm outward, and grasps an atlatl in the throwing position. The left arm also slopes downward from the shoulder, but the left hand is turned downward and back and apparently grasps four darts.

Other elements common to all of these Tlaloc figures are: a headdress, a spiky, tiara-like feature on the brow; earplugs; round eyes outlined by flat fillets; a sharp, protuberant nose; a heavy mustache-like upper lip turned downward at the outer ends; four large upper incisors; no chin; a pectoral pendant suspended from a cord (?) encircling the neck; a trifoliate kiltlike garment, the center element of which reaches to below the knees; and two legs ending in small feet, the heels of which are affixed to the outer surface of the vessel with the instep resting on the upper edge of the basal decorative band.

The upper and the basal horizontal decorative bands show a succession or chain of concave discs between two raised ridges. Vessels 1 and 3 portray these discs as though they were the round links of a chain.

The principal differences of decorative elements occur in connection with the headdress, the pendants, the atlatls, and the ribbon-like adornments attached to or immediately behind the arms of the Tlaloc figure.

The headdresses of the figures affixed to Vessels 1, 2, 3, and 5 are essentially alike, though presenting individual differences of details. For example, those of Vessels 2 and 5 seem to include feathers, indicated by incising and (Vessel 5) small lumps, as well as by the bent-over, somewhat wavy appearance of the upper portion of the headdress. The pendants suspended over the breast of Tlaloc are of two main forms: a rectangular slab, partially divided in two by incisions extending inward from the narrow edges (Vessels 1 and 3), and an element resembling a curvilinear W (Vessels 2, 4, and 5).

The atlatls represented on Vessels 3 and 4 were anciently damaged and their original form cannot now be determined. But those preserved on the three other incensarios are intact. That of Vessel 1 was bent in a shallow S curve, the right hand of Tlaloc grasping the stick at about its center. This atlatl shows no groove, nor any protuberance against which a dart might have been placed for launching. The other two examples, however, are much more detailed and each shows a lump or knob at its upper end. All three are broader and flatter at the upper than at the lower ends. The atlatl of Vessel 5 separates two pairs of what may have been intended to represent smaller atlatls, all held in Tlaloc's hand.

Vessels 1, 2; and 5 show, on both sides of the Tlaloc figure, from about its shoulder height to its heels, two broad "ribbons," which are crossed or joined together at the elevation of Tlaloc's upper arms. Vessels 1 and 2 bear, at the point of this crossing, a knot or perhaps rosette of some kind which seems to affix the ribbons to the figure's arms. The ribbons of Vessel 5, on the other hand, lack "knots" and the ribbons themselves appear to pass behind the arms. Vessel 4, which also bears these ribbons, though here shown by deep incisions rather than in bas-relief, likewise lacks any suggestion of a knot, and the arms are again shown to be in front of the ribbons. Vessel 3 lacks any kind of ribbons.

COMMENTS

The position of the Baratta incensarios in time and space is difficult to determine, owing in part to our rather dubious information of their provenience and in part to the scarcity of closely comparable vessels.

As far as I am aware, after examination of perhaps 10,000 specimens of pre-Colombian pottery in Salvadoran collections, only one fragment from

94.1. Tlaloc incensarios in the Baratta Collection. Vessel 1: height, 35.5 cm; rim diameter, 27 cm; Vessel 2: height, 43.5 cm; rim diameter, 26 cm.

a similar vessel has so far come to light within El Salvador itself. This large sherd, in the Salazar collection, is believed to have been found in the area of Suchitoto in the Lempa Valley.

Tall, annular-based incense burners, though lacking the basic hourglass form of the Baratta specimens, were discovered in some numbers at the Campana-San Andres site. There such vessels were associated with ladle-form, tripodal incensarios which possessed long handles decorated with grotesque serpent heads. Stratigraphically there is no

doubt that both of these forms are late at San Andres, probably representing a postconstruction phase of occupation of that ruin. Such specimens removed from Altar A of that site are almost certainly post-Copador in age, thus datable to some period after 9.16.5.0.0, perhaps roughly contemporary with Tohil plumbate. Somewhat inconclusive evidence furnished so far by carefully excavated sites in western El Salvador suggests that vase incensarios of the general dimensions of those found at San Andrea and in the Baratta collection lack the antiquity of the

94.2. Tlaloc incensarios in the Baratta Collection. Vessel 3: height, 39 cm; rim diameter, 25.5 cm; Vessel 4: height, 40 cm; rim diameter, 27 cm.

earliest ladle forms. Furthermore, of those known in El Salvador, earlier versions of vase incensarios are considerably shorter in proportion to maximum diameter.

Of decorative elements, perhaps the Tlaloc heads affixed to or modeled on the sides of certain rather crude clay bottles from central El Salvador bear the closest similarity to the Tlaloc features of the Baratta incensarios. These bottles, noted by Lothrop (1927:194ff, Fig. 15,11) and included in vari-

ous private collections, are distributed throughout the area between ancient Cuzcatlan and the Lempa River. "Associated with them in the ground are life-size images of frogs, sacred to Tlaloc . . . also incense burners with long serpent handles . . . recalling incense burners found in central Mexico or those portrayed in Aztec codices; likewise figurines of sub-Maya stamp . . . as well as portrait jars . . . and burial urns" (Lothrop 1927:195, 196). This ceramic complex Lothrop attributes to the Pipil Indians, whose arrival

94.3. Tlaloc incensarios in the Baratta Collection. Vessel 5: height, 46 cm; rim diameter, 32.2 cm; (a) back of Vessel 4, showing lack of bottom; (b) base of Vessel 6, showing interior flange support for disc-shaped removable bottom.

in El Salvador he places at between 1100 and 1200 A.D.

If we accept Lothrop's evidence and suggestions for dating the aforementioned "ceramic complex," we may be justified in assigning the Baratta incensarios to Pipil times and, presumably, inspiration for the following reasons: (1) The provenience given for these vessels, even though correct only for the general area involved, falls within what was anciently the principal zone of Pipil rule in El Salvador. (2) The only reasonably comparable specimens likewise proceed from this area. (3) Ladle incensarios with serpent-head handles, contemporaneous with large vase incensarios at San Andres and demonstrably late at that site, are likewise contemporaries

of Tlaloc bottles, the principal decorative motif of which is closely similar to the Tlaloc heads of the Baratta incensarios. (4) Tlaloc motives of this style and execution find reasonably close counterparts among ceramic manufactures ascribed to peoples of supposed Nahuatl speech of late prehistoric times, in El Salvador identified as the Pipil.

On the other hand, evidence from Tazumal in western El Salvador, arid Kaminaljuyu in Guatemala, suggests that cultural connections between the inhabitants of the central plateau of Mexico and dwellers on the Pacific slopes and highlands of Central America were well established long before Pipil times. In view of the antiquity of Tlaloc worship in Mexico, plus the numerous and varied rep-

resentations of this god found at many ruins lying between that country and El Salvador, covering a time span of perhaps more than 1000 years of the pre-Columbian Christian Era, one may well hesitate to assign vessels whose stratigraphic position is unknown to any definite period of prehistory. Again, the fact that tall vases with hourglass contours have yet to be excavated from early levels of carefully dug sites in El Salvador does not automatically rule out their existence in such strata. In Guatemala, for example, basically similar forms are dated by Butler (1940, Pl. VI, j) to Chipal I, perhaps several centuries before the traditional entry of the Pipil into El Salvador. Cylinder forms with vertical flanges and appliqued faces and figures are even earlier at Kaminaljuyu (Kidder, Jennings, Shook 1946, Fig. 201g. Unfortunately, no Salvadoran Pipil ruin has yet been thoroughly examined by competent archae-

ologists; consequently, certain objects now attributed to that poorly known civilization may later prove to pertain to other times and fabricants.

Aside from the manifest need for further excavation, however, a line of research which might today prove of aid in fixing the antiquity and ethnic origin of the varying forms and decorations of incensarios in Mesoamerica is a careful technological examination of all specimens from specific levels and positions in carefully excavated ruins. At the present time, no general presentation of this material is available, though many of the necessary facts are available in the numerous reports and articles which have been published during the past fifty years. Lacking such a synthesis of documented specimens, the field worker without access to a large archaeological library cannot securely place his discoveries in their proper historical perspective.

Certain Archaeological Specimens from Guatemala II

A. V. Kidder

Like specimens from Guatemala recorded in an earlier paper in this series (Note 92), the objects here described are incidental finds, purchases, or gifts and therefore will not be included in reports dealing with Carnegie Institution's major archaeological undertakings. All are now in the Guatemala National Museum.

Figurine arm from Kaminaljuyu (Fig. 95.1a). A surface find, this finely finished whiteware arm from a jointed figurine is doubtless of the Archaic Miraflores Phase. A leg of the same ware and finish, also from Kaminaljuyu (Fig. 92.5e), possesses a similar perforated protuberance designed to fit into a cup in the body of a figurine. In that case it was inferred that each leg was attached separately but the longitudinal grooves on either side of the present specimen's protuberance might indicate that a string passed through the body to the other arm. No figurine body with cups such as would be necessary to receive arms or legs of this sort has been reported from Kaminaljuyu or, as far as I know, elsewhere. The drawing is natural size, by Antonio Tejeda F.

Problematical pottery objects (Fig. 95.1c). Collected by A. L. Smith in 1949 at Pantzac, a site near San Andres Sacabaja, Dept. of El Quiche, which, because of presence of Tohil plumbate sherds and absence of recognizable earlier or later pottery, is assignable to first part of Postclassic period. They are heavy star- and ring-shaped objects of gray to light brown, unslipped ware, backs flat and fairly well smoothed.

Average thickness, disregarding the slightly raised edges of some, 2.5 cm; original diameter of lower right probably about 45 cm of lower left apparently somewhat greater, because of larger central opening. Although numerous, approximately contemporaneous Guatemala highland sites have been examined by Mr. Smith and others, no similar specimens have been found in any of them. Mr. J.E.S. Thompson has called my attention to what are undoubtedly the same sort of objects from Teotihuacan: baked clay models, greatly enlarged, of cross sections of conch shells. Three of these are illustrated by Peñafiel (1900, Pls. 44-46; that in Pl. 46 here shown, much reduced, in Fig. 95.1b). Mr. Thompson tells me that the cross section of the conch was the special attribute of Quetzalcoatl and of his ally Xolotl. White lime plaster adheres to back of the specimen at upper right, as if it might have been mounted on a wall as an architectural ornament.

Carved jades (Fig. 95.2a). Said to be from La Nueva, Dept. of Jutiapa. *Left*: light green; soft unaccented relief, T-shaped nose, necklace in same line with earplugs, faces in profile at upper corners, are traits of Early Classic jade carving (see Smith and Kidder, MS), but small perforations in beads in necklace not previously noted in specimens of that period. Transverse biconical perforation at eye-level; three 1 mm perforations in edge of back, one on either side at earplug-level, one at lower point. Back polished. Width 6.8 cm. *Center*: light green; edge broken away all around and cursorily reworked. Back polished. Oblique measurement 11 cm, thickness 3-

95.1. Archaeological specimens from Guatemala.

3.5 mm. *Right*: earplug flare (?), very fine dark green, high polish both sides; four serpent heads facing outward. Diameter 6.3–6.4 cm; thickness 3.5 mm.

Polychrome vase (Fig. 95.2b). Collected by A. L. Smith from a looted tomb at the ruins of Tzicuay on Brol Brothers' Finca San Francisco, near Cotzal,

Dept. of El Quiche. Decoration in dark red and black on medium gloss orange slip, which also covers interior nearly to bottom. Red rim-band carries over squarish rim, extending 1 cm into interior; 4 mm below interior red is a red encircling line 3 mm wide. Exterior design on either side a deer, the two separated by vertical panels representing three-strand braids. Diameter of orifice 13.2 cm. The piece is of interest because of rarity of deer in pottery decoration; examples: Nebaj (Smith and Kidder, MS., Fig. 71a), Ilom (Termer 1931, Fig. 5s), Yucatan (Bliss 1947, Fig. 137). For representations in codices, see Tozzer and Allen (1910). Because the tomb had been used for a long time and had contained Early, Late, and Postclassic (Tohil plumbate) pottery, the period of present piece uncertain, probably Late or Postclassic.

Incense burner and cover (Fig. 95.2c, d). From finca at Zumal, Dept. of El Quiche, belonging to Diego Brito Perez, who presented specimen. Unslipped reddish brown. Head and body of extended jaguar on cover are hollow, a round 5-cm hole opening into interior, presumably to allow smoke to enter body and pass out of mouth. Two vertical pairs of "spikes" on either side of cover and of body. Period unknown. A similarly extended jaguar appears on cover of incense burner from an Early Classic (Esperanza Phase) structure at Kaminaljuyu (Kidder, Jennings., and Shook 1946, Fig. 192b). Greatest diameter of cover 25 cm.

Face on wall of incense burner (Fig. 95.2e). Gift of David Herrera of Aguacatan, Dept. of Huehuetenango. Specimen probably from nearby ruin of Chalchitan. Ruddy brown ware, unslipped. Face moldmade, accessories appliquéed. Face painted red (white is lime deposit); buttons encircling earplugs and around face bear traces of blue paint. Vessel probably cylindrical, perhaps with pedestal base. Diameter orifice about 42 cm, height of fragment 26 cm.

Question of incense burner "spikes." From at least Early Classic times until the conquest, many forms of Mesoamerican incense burners bore small rounded or, more commonly, pointed protuberances (Fig. 95.2d, f, g). Their frequent use during many centuries on ceremonial vessels of wide geographical distribution seems to imply some definite symbolic significance. It is here suggested that they may represent the very similar protuberances that appear, in the early stages of its growth, on the ceiba (bark shown in Fig. 95.2y), a tree long held sacred by the Maya (Redfield 1936). Mr. Thompson has suggested to me that they might represent nodules of copal such

as the modern Lacandon use (Tozzer, 1907:125, Pls. XXIII, XXIV) and which also appear on large lumps of copal from the Sacred Cenote at Chichen Itza. The "spiked" vessels here shown are probably Late Classic: one a shallow bowl from an unknown locality in Guatemala, the other a late post Classic fragment from Chuitinamit Atitlan, Dept. of Solola. The former (Fig. 95.2f) is of a type of which many examples have been found in Lake Amatitlan, into whose waters they had evidently been cast as offerings. Like many incense burners, it bears thin, white, apparently post firing paint. Diameter 24.8 cm. The fragment (Fig. 95.2g) is from a large, thick-walled incense burner. Original diameter probably over 50 cm.

Figurine whistle (Fig. 95.3a). Purchased from Barnum Brown at Altar de Sacrificios, a Classic lowland Maya site at junction of the Salinas (Chixoy) and Pasion Rivers, Dept. of El Peten. Chocolate-brown pottery, protruding mouthpiece at rear base, two 5 mm-round "stops" in back at level of neck cloth tie. Rectangular shield, hafted celt. Entire front moldmade, bank modeled. Total height 15 cm. Period uncertain; in this connection it may be noted that a Tohil plumbate sherd was found by E. M. Shook at Altar de Sacrificios in 1937, the only occurrence of this Postclassic ware so far reported from El Peten.

Moldmade head (Fig. 95.3b). Collected by R. E. Smith in a Late Classic deposit at Chipoc, near Coban, Dept. of Alta Verapaz. From a hollow figurine, presumably a whistle. Flat band over forehead and mouth of serpent (?) headdress red; human face and head of serpent (?) lighter red; traces of blue on feathers (?) at right. Height 6.5 cm.

Face from wall of incense burner (Fig. 95.3e). Provenience and period unknown. Unslipped brown. Hollow; opens below edge of necklace, therefore evidently not part of a complete figure. Note unique nose-ornament and similarity of eyes and earplugs to those of Fig. 95.2e. Width "as is" across earplugs 17 cm.

Cover of small incense burner (?), Dieseldorff Collection (Fig. 95.3e). Provenience and period unknown. Unslipped brown, well smoothed. Rounded edge of open base shows wear; 4 mm orifice (smoke vent?) in conical top. Unique specimen. Height about 8 cm.

Water pipe of jar necks (Fig. 95.3f). Collected by R. Redfield and A. V. Kidder at a spring near Agua Escondido, Dept. of Solola. Three of five jar necks

a

b

c

d

h

95.2. Archaeological specimens from Guatemala.

95.3. Archaeological specimens from Guatemala.

placed end-to-end as if to form a drain or conduit running downward from spring on sloping ground. Shape and ware of necks same as those of Late Classic (Amatole Phase) jars from Kaminaljuyu. Specially made pottery pipes set vertically end-to-end and leading down to a large perforated jar that served as a cistern were found by Ricketson (1935) at Quirigua.

Doughnut-shaped vessel (Fig. 95.3d). Purchased at San Marcos, Dept. of San Marcos. Heavily weathered, dark red, medium gloss slip over whole surface; black decoration outlined with post-finish incising. Broken-off spout opposite animal head evidently rose nearly vertically. Probably pre-Classic. Diameter, exclusive of head, 21 cm.

Rectangular vessel (Fig. 95.3g). Purchased at Kaminaljuyu and presented by William Foshag. Red-

dish brown, possibly slipped; smooth matte finish; thin white, post-firing paint on eyes, lower part of nose, fangs, flat rim. White also applied to ends and back to represent moldings of same 1.5 cm width as fillet-moldings on front. Print of woven mat (over-two under-two twill, elements 4 mm wide) on interior of sides and ends and exterior of bottom, indicating that five slabs were made separately and welded together to form vessel. Length 20, width 12, height 8 cm; walls 1.2 cm thick. A deep vertical-walled, flat-bottomed bowl and a small simple silhouette bowl, both heavy and unslipped, with traces of thin white paint, were found, according to vendor of all three, with rectangular piece. Probably Early Classic (Esperanza Phase), as flanges and other flat parts of Esperanza incense burners were also made of clay patted out or pressed down on mats (Kidder, Jennings, and Shook 1946:212).

Tlaloc Effigy Jar from the Guatemala National Museum

Stephan F. de Borhegyi

The large Dieseldorff Collection, donated to the Guatemala National Museum in 1942, includes many fine specimens, most of which, unfortunately, are of unknown provenience. The anthropomorphic jar representing a bearded individual, with which this paper is concerned, is believed to have come from Kaminaljuyu, the large archaeological site near Guatemala City. No other information concerning the association and age of the specimen is available.

The jar is of coarse, unslipped, reddish brown ware, the surface unpolished but fairly well smoothed. The paste is a warm brown, showing small particles of white temper. The flaring rimmed, straight necked jar has a spherical body, slightly recurving at the base. The nose, eyebrows, and ears of the individual represented are modeled. The other details are applied (Fig. 96.1a).

The heavy eyebrows forming a semicircle around the eyes, the upcurving scrolls on either side of the vertically grooved beard, as well as the prominent aquiline nose, are characteristics generally associated with the Mexican rain god, Tlaloc. This resemblance is interesting in view of the fact that a similar jar from the Early Classic horizon has been reported from Kaminaljuyu (Kidder, Jennings, and Shook 1946, Fig. 200q, r). This specimen (Fig. 96.1b), accompanied by another jar identical but crushed beyond repair, was found in Tomb II of Mound A during the excavations by Carnegie Institution in 1937. Both were recognized as representations of Tlaloc and were assigned to the Esperanza Phase at Kaminaljuyu. It is believed that the site was under

Teotihuacan religious influence and possibly even political control at that time. The close similarity in shape, technique, and ware to the specimen from a controlled excavation enables us to place the Dieseldorff jar, at least tentatively, on the same time level.

Certain interesting differences between the two specimens, however, should be mentioned. (1) Figure 96.1a lacks the tripartite headdress which has broken off from the rim, as shown by the line of fracture. This, as well as the "tri-mountain symbol" seems to be often, if not exclusively, connected with Tlaloc representations (Kidder, Jennings, and Shook 1946, Figs. 102a; 169a, b; 175a; 199l; 200q, r; 207a). (2) The applied scrolls, the beard, and the aquiline nose of Figure 96.1b are considerably longer and of cruder workmanship than those of Figure 96.1a. (3) The earplugs of Figure 96.1b do not have central depressions; the hand shows no indication of fingers as do the hands of the other. (4) A vertical, solid roll of clay, with outcurving end, connects the rim of the jar with the left shoulder of the Figure 96.1a, effigy. Strangely enough, the right shoulder shows no sign of similar treatment. It seems, therefore, that this extension existed only on the left side. A Tlaloc effigy jar from Teotihuacan (Kidder, Jennings, and Shook 1946, Fig. 169, 2) has a similar but crooked roll of clay connecting the right shoulder with the rim. Unfortunately, the significance of this strange object on the shoulder of each specimen is problematical. It may represent an atlatl, a snake, or a streak of lightning, all frequent attributes of Tlaloc. The outcurving

a

b

a'

b'

96.1. Tlaloc effigy jars: (a) anthropomorphic jar, with sectional view; Dieseldorff Collection, Guatemala National Museum, no. 5177; height, 18 cm; diameter, 14.5 cm; (b) anthropomorphic jar from Kaminaljuyu, with sectional view (Kidder, Jennings, and Shook 1946: fig. 200r), Guatemala National Museum, no. 2433, total height 19 cm, diameter 15 cm.

end of the otherwise straight clay roll of Figure 96.1a would suggest a conventionalized representation of an atlatl. (For the association of Tlaloc with the atlatl see Boggs 1949, Figs. 1, 2, 3; Kidder, Jennings, and Shook 1946:221, Fig. 204a). (5) The little jar under the left arm of Figure 96.1, a is also a well known attribute of Tlaloc. The codices often represent this rain god holding a small jar, sometimes of jade, in his hand, or pouring water from it, a symbol by which his power to produce rain is demonstrated (Caso 1936:25, Fig. 14).

It is interesting to note that Cocijo, the Zapotecan counterpart of Tlaloc, is frequently represented on the funerary and effigy urns from Oaxaca as seated, and holding in his hands a small, outcurving rimmed jar identical in most respects to the jar held by the Tlaloc in Figure 96.1a (Linné 1938, Pls. 28a, d; 29a, b, c).

The Tlaloc effigy jars of the Esperanza Phase at Kaminaljuyu, together with many other ceramic features, are believed to indicate a Teotihuacan influence from the north (Kidder, Jennings, and Shook 1946:208). In 1946, when this report was published, no definite evidence of communication between the great centers of Oaxaca, in particular Monte Alban., and Kaminaljuyu had been established, although a strong contemporary relationship had been shown between the Monte Alban III and Teotihuacan III periods by Caso (1938). The lack of stronger ties between Oaxaca and Guatemala seemed explainable only by the mountainous nature of the intervening area or by the warlike behavior of the Oaxacans, and it was proposed that the influence from Teotihuacan might have detoured via Veracruz on its

way to Kaminaljuyu (Kidder, Jennings, and Shook 1946:257).

A recent publication by Ignacio Bernal (1949) has brought to light new evidence of cultural connections between Monte Alban IIIA, Teotihuacan III, and the Esperanza Phase at Kaminaljuyu. Among the specimens illustrated by Bernal are two Tlaloc effigy jars from Tombs 95 and 137a at Monte Alban (Bernal 1949:9–11, Figs. 20, 21) which bear certain similarities to the specimens dealt with in this paper and in addition have several points of resemblance to specimens illustrated by Kidder, Jennings, and Shook (Fig. 169a, b) from Teotihuacan. Both the Tlaloc effigy jars from Monte Alban have been assigned by Bernal to the Monte Alban II–IIIA Transitional period, which is coeval with early Esperanza and Teotihuacan III. His Figure 21 bears the tripartite headdress already noted on specimens from Teotihuacan and Kaminaljuyu and. also has the remains of a solid vertical clay roll applied to the right edge of the jar rim in much the same way as in our Figure 69.1a and on the Tlaloc effigy jar from Teotihuacan (Kidder, Jennings, and Shook 1946, Fig. 169a). Further similarities can be found between these jars and those of Tehuacan (Kidder, Jennings, and Shook 1946, Fig. 202e) and Xolalpan (Linné 1934:66–68, Figs. 31, 34, 40).

This evidence alone might go a long way toward establishing stronger cultural ties between Oaxaca and Kaminaljuyu but until more information has been obtained from the interlying areas of Chiapas and western Guatemala, it can only be suggested that at least one, and perhaps the major, route by which Teotihuacan influence reached Guatemala was by way of Oaxaca and the Pacific slope.

GUATEMALA CITY

Rim-Head Vessels and Cone-Shaped Effigy Prongs of the Preclassic Period at Kaminaljuyu, Guatemala

Stephan F. de Borhegyi

In July 1949 I received a grant from the Viking Fund of New York to organize the study material of the Museo Nacional de Arqueología y Etnología of Guatemala. While engaged in the organization of the large figurine collections, composed of material from the Dieseldorff Collection, the "desconocido" or unreliably recorded material of the Museum, and the collections donated by the Carnegie Institution of Washington, I encountered some unusual specimens deserving of special notice.

On examination it appeared that much of what had formerly been considered part of the Preclassic figurine complex of the Guatemalan highlands was actually part of the "rim-head" vessel complex described by Kidder and Shook (Note 69). In that publication the authors were able to place a group of remarkably uniform, hollow, bald, human heads, from flat-bottomed tripod vessels, in the Miraflores Phase, the oldest culture then recognized at Kaminaljuyu. It was believed that these vessels served a ceremonial purpose and were undoubtedly related to ones with three similarly placed but smaller "rim-heads" found in later horizons on the south coast of Guatemala, El Salvador, Honduras, and Mexico (Kidder Note 15). Therefore the former were designated as "rim-head" vessels but of a type peculiar to the Miraflores culture. Hereafter in the present Note this homogeneous group will be referred to as Type A. No variations of this type had been recognized by Kidder and Shook.

While organizing the Dieseldorff figurines I ran across some solid, human, head fragments (Fig.

97.1a, c, d) which showed a striking facial and technical resemblance to the previously described Type A rim-heads. These fragments were made from the same coarse, unslipped, reddish brown ware, the paste of which was a warm brown and thickly sown with particles of white temper. The major difference, however, was that all the head fragments were solid instead of hollow. On closer examination it appeared that, to judge from the angle of breakage, these heads could never have been attached to figurine bodies but must have been applied to the side of some vessel. With these fragments as a basis, similar ones were identified in the Hartwell M. Webb Collection (Fig. 97.1e, g) and collections of unknown provenience in the Guatemala Museum (Fig. 97.1f). All were solid and bore the characteristic slightly swelled cheeks, out-thrust chin, prominent nose to which pellets of clay had been added as a representation of nose buttons or nostrils, and protruding eyes made by the application of a round or elliptical button of clay set into a shallow, horizontal depression. The supposition that all came from Kaminaljuyu was strengthened when comparison was made with the same uniform type of solid heads found at Kaminaljuyu by the Carnegie Institution (Fig. 97.1b, h, j, l) and at Las Majadas, a section of Kaminaljuyu, by Lic. David Vela (Fig. 97.1i, k).

The question of the type of vessel and the proper orientation of the heads on it was still unsolved until I was fortunate enough to find in the Dieseldorff Collection two pieces which I consider to represent the original appearance of the solid, human, head

fragments (Fig. 97.2a, b). Both specimens bear the same relationship to tripod, flat-bottomed bowls as do the rim-heads of Type A. The most striking and significant difference, however, was that here a solid head had been applied to a large, upright, hollow bulb instead of the human features appearing on the bulb itself. They were therefore classified as Type B of the "rim-head" vessel complex. For a probable restoration of Type B in comparison with Type A (Kidder and Shook 1946, Fig. 1a) see Figure 97.3.

Type A, as described in Note 69, is uniformly bald and lacking in headdress. Since then some exceptions to this type have appeared (Fig. 97.4f, g, i). These have an appliqué headband, two being rippled, with a central ornament usually consisting of a button of clay. This subtype shows a further connection with some of the specimens of Type B (Fig. 97.1a, f, g, i).

Another form depicts the pouting individual in profile (Fig. 97.4a–e, h). Of these six, three are hollow (Fig. 97.4a, e, h) and three are solid (Fig. 97.4b, c, d). That shown in b is highly conventionalized; d appears to be reclining, his head resting on his hand. The rectangular, depressed eyes, headdress, and mouth of d strongly resemble Figure 97.1.1. Although these heads do not form as homogeneous a group as Types A or B, because they carry certain characteristics of both, the fact that they are all in profile makes it advisable to class them separately as Type C.

Unfortunately, the chronological relationship of the three types is not known; we know at present only that they were different manifestations of the same idea, although a hypothesis based on the greater sophistication of the conventionalized profile form might consign this type to a later stage of development. At the moment, all the specimens thus far described are believed to belong to the Miraflores Phase at Kaminaljuyu and in particular to the Providencia (rarely), Verbena, and Arenera subphases. They are apparently lacking in the Santa Clara, or latest, subphase.

It should be mentioned that some specimens of Type B (Fig. 97.1d, e) differ from the others in having a wide open mouth, which gives them a certain resemblance to a jaguar or "tiger" face. This characteristic has been linked to the Olmec "baby face" by Vaillant (1940) and more recently by Covarrubias (1944). This similarity between the solid-head types and the Olmec "baby face" becomes more interesting when we recall the earlier observation by Kidder and Shook that the bald head and up-turned lip of the hollow rim-heads bear similar resemblances to the representation of the human head in Olmec art.

97.1. Rim-heads, Type B, Kaminaljuyu: (a, c, d) Dieseldorff Collection (Guatemala National Museum); (e, g) Hartwell M. Webb Collection (Guatemala National Museum); (f) of unknown provenience (Guatemala National Museum); (i, k) private collection of Lic. David Vela, found at Las Majadas, a section of Kaminaljuyu; (b, h, j, l) excavated by the Carnegie Institution of Washington (Guatemala National Museum); (b, h) Mound E-III-3; (j) Mound E-IV-4; (l) arenal, near Mound E-III-3; (f', h', k') sectional views of f, h, k. Remains of white slip shown on c, f, i, j, k. Note the open mouth of b, d, e, f and the rectangular, depressed eyes of l. Height of k, 90 cm.

CONE-SHAPED EFFIGY HEADS FROM KAMINALJUYU

Bearing a probable parallel relationship to the rim-heads of the Miraflores culture are the three-pronged effigy incense burners of the Preclassic horizon.

Our present knowledge of the ceremonial function of such pieces is very incomplete. We know (Shook, publication in preparation) that one type existed with vertical side-flanges and three plain, solid or hollow, conical prongs on the top and human effigy heads on the body (Fig. 97.6b). On the other hand, we have hollow, cone-shaped human heads presumably serving the same purpose as the plain prongs but because they have not yet been found at Kaminaljuyu with the rest of the incensario it is

97.2. Rim-heads, Types A and B, Kaminaljuyu: (a, b) Dieseldorff Collection (Guatemala National Museum). (a', b') left and right side views of a, b; (a'', b'') sectional views of a, b; the vents shown in section as at back of head are actually just below the right shoulder (a) and behind the left ear (b). The solid, truncated, conical foot of b has been broken off at the base; remains of white slip on a; note the hunchbacked appearance and the pectoral pendant of b; height of b, 20 cm.

not known if the bodies of these vessels bore additional effigy heads. For suggested restoration see Figure 97.5d', f' and caption. One complete example of this type, found near Chiquimulilla, Department of Santa Rosa, Guatemala, bears no additional effigy heads or flanges (Fig. 97.7a). The fact that the effigy incensarios were three-pronged, as were also the rim-head vessels just described, led me to suspect a parallel connection both in stylistic technique and in ceremonial function. Both the plain and effigy prongs were made from a coarse, reddish brown to gray ware and paste similar to that of the rim-heads, both solid and hollow types. Little can be inferred as to the ceremonial functions of these two types of vessels but definite facial characteristics common to both the rim-heads and the effigy prongs are to be noted. The most common and impressive points of resemblance are illustrated in Figure 97.5: appliqué but slanted eyes (a, b, d, e); the presence of nose-button (a–d); the characteristic pouting mouth (e, f); and the occurrence of a headdress with a central ornament extending to form a vertical flange on either side of the head. In this connection, special comparison should be made between Figures 97.5b and 97.1f as well as between Figures 97.5a and 97.4e.

Present also at Kaminaljuyu and probably from the pre-Classic horizon are huge stone "altars."

97.3. Rim-head vessels, Type B, Kaminaljuyu: (a, b) Type B vessels; restoration based on fragments shown in Fig. 97.2a, b; (c) Type A vessel (after Kidder and Shook 1946: fig. 1a).

They originally bore three large top prongs, which are now broken off at the base, and are as yet of undetermined culture and function (Fig. 97.6a). They may well represent a similar manifestation of this complex.

It is my opinion that the three prongs of the pottery incensarios and stone "altars" served the same purpose: supports for another vessel during some kind of religious performance. Definite signs of wear on the exterior surface of the tips of both the plain and effigy prongs suggest a type of vessel with

97.4. Rim-heads, Types A and C, Kaminaljuyu: (f, g, i) Type A rim-heads; (a, b, c, d, e, h) Type C rim-heads; (a, c, d) Dieseldorff Collection (Guatemala National Museum); (h) private collection of Harold Martin; (b, f, g, i) Carnegie Institution; various parts of Kaminaljuyu (Guatemala National Museum). Remains of white slip visible on b, c, e, f, i, and traces of yellow paint remain on top of head. Circular vents on back of head (h, i) and behind the right ear (a, f). No vents on b, c, d, e, g. Note the prominent aquiline nose of the specimens. Height of i, 90 cm.

a wide, overhanging rim which would have rested on these prongs. There is just such a vessel in the Preclassic horizon. They have been named "grater bowls" because of their deeply grooved inner surface (Shook, publication in preparation, probable restoration in Fig. 97.6c, c'). Although there is no definite proof, it seems likely that these bowls were used in combination with the incensarios. They are made from the same coarse, reddish brown to gray ware, and are deeply grooved on the rim and interior surface in the same manner as are the conical effigy heads. It is hard to say what might have been the original use of these bowls; perched as they were

97.5. Cone-shaped effigy heads from incensario vessel supports, Kaminaljuyu: (a, b, c, e, f) Carnegie Institution of Washington; collected and excavated from various parts of Kaminaljuyu near the Roosevelt Hospital and Finca Las Charcas; (d) Dieseldorff Collection (Guatemala National Museum); (d', f') suggested restorations of d, f. All specimens have or had an opening to the outside through the mouth or through a large hole directly below the mouth. Note the peculiar tool-indented fillet head-dress and the flanges. Height of d, 14.2 cm. Concerning the suggested restoration of d' and f', it should be mentioned that one rim fragment of a three-pronged incensario support was found on the surface near the Roosevelt Hospital (Las Charcas, Pit 3), Kaminaljuyu vicinity. This specimen bears three rows of red-painted spikes immediately below the top surface. Below the spikes is evidence of rectangular openings similar to the triangular ones of Fig. 97.7a. The remains of an effigy prong showing the function with the rim is also similar to the Chiquimulilla specimen. Around the openings, remains of a white slip are still visible. This suggests that the incensario body connected with the Las Charcas effigy prongs is similar to the specimen shown in Fig. 97.7a. To associate this fragment definitely with the Las Charcas culture is unwise because it is a surface find and the proper association and age of the Chiquimulilla specimen are not known. It is hoped that further stratigraphic excavation will clarify this point.

high on the tops of incensarios, they would seem to have contained an offering to the gods. It should be noted, moreover, that the grooved interior surfaces show no signs of wear but are heavily fire-blackened, which further connects them with the incensarios and makes it hard to believe that they could have been used for such utilitarian purposes as graters.

The faces of the stone "altars" and the effigy prongs from the pottery incensarios bear certain characteristics often associated with the conventionalized, sometimes feline, portrayal of the Kaminaljuyu rain god. Although the faces of the conical effigy

heads are far from uniform, as was the rim-head material, all show some characteristics of that deity, as seen in Figure 97.5; namely, deeply grooved "tear streaks" (b, e, f), pointed goatee (b, d), nose button (a-d), a strong oblique line from either side of the nose to the jowl (a, c, d), circled eyes and outstretched tongue (d), and a headdress with a central ornament which extends into vertical side-flanges. It has been pointed out that some of the rim-heads have a similar form of headdress; those which are bald have short side flanges in the form of ears, and very probably nose buttons rather than nostrils are

97.6. Three-pronged incensario vessel supports and stone "altars," Kaminaljuyu: (a) "Altar" V, Guatemala National Museum; found at La Providencia, a section of Kaminaljuyu, museum no. 2046; height, 85 cm, diameter, 76 cm, basal diam without prongs (now broken off) 17 cm; volcanic tuff; headdress terminates in a knotted band at back of head and there are traces of red paint; (b) large, three-pronged pottery incensario, Guatemala National Museum; donated by Rafael Pinol from Finca Las Charcas, a section of Kaminaljuyu, museum no. 3625; height 110 cm, diameter 30 cm, height of prongs 22 cm; remains of white slip; a human face appears on upper half of body; on the lower half is a jaguar head with bifurcated tongue and two curving fangs; note the vertical side-flanges and the "fish-tail" protuberance on top; (b') sectional view of b; (c) suggested restoration of the "grater bowl" believed to be the vessel used in connection with the three-pronged incensarios and supported by the prongs; fragments excavated by the Carnegie Institution near Roosevelt Hospital, Guatemala City; height of bowl cover 9 cm, diameter of bowl cover 29 cm; (c') sectional view of c.

97.7. Three-pronged incensario vessel support, Chiquimulilla, Guatemala: (a) three-pronged incensario vessel supports found in a lake on the finca of Lic. Faustino Padilla near Chiquimulilla, Department of Santa Rosa, Guatemala; museum no. 1195; total height 37.5 cm, diameter 21 cm, height of prongs, 11 cm (shown inverted in Kidder, Jennings, and Shook 1946: fig. 202c); (a') sectional view of a; remains of red paint and white slip on body. Note the crudely modeled, bearded individual and the tool-indented fillets on the hollow, conical prongs.

represented by the pellets on either side of the nose. Even more interesting, however, is the fact that two rim-heads have very possible "hear streak" representations. One from Type A (not illustrated) has a pair of red vertical lines painted beneath each eye; the other, Type C (Fig. 97.4c), has an appliqué band from eye to chin. If these effigy prongs are indeed representations of the Kaminaljuyu rain god and if our feeling is correct that between the effigy prongs and the rim-heads there is a parallel connection, then it can be assumed that the rim-heads depict the same deity or that there is a close relationship between the "tiger-faced" god, the Olmec "baby face," and the Kaminaljuyu rain god.

THEORETICAL RECONSTRUCTION OF THE USE OF INCENSARIO SUPPORTS AND RIM-HEAD VESSELS DURING THE PRECLASSIC PERIOD AT KAMINALJUYU

It seems advisable to collect and discuss individually the arguments for some of the specific points mentioned above. As many of the hypotheses were made on a theoretical basis as well as on analysis of the material at hand, there should be explained the ideas leading to their formulation. I hope that this

will stimulate criticism and thereby affect progress through the contribution of other workers in this field. Let it be understood that my conclusions are not to be considered final explanations but merely attempts to pull together a great many scattered ideas into a picture; the canvas depicting some new conceptions of the religious-ceremonial features present in the early agricultural period in Middle America and the frame binding it into a whole, consisting of the previously described group of cultural objects from Kaminaljuyu. Therefore, I hope to give a fuller explanation of the use and religious significance of these objects, both rim-head vessels and especially incensarios. These vessels had a very long and complex history; knowledge of their use and change through the centuries requires detailed study. Here I attempt only to suggest their connection with rain and rain deities during the early stages in the development of the complex. I have done this in the belief that some kind of explanation is better than none.

It has already been suggested that the prongs of the three-pronged incensario were used as supports for a bowl. What are the arguments which lead to this conclusion? First of all, the tips of the prongs actually show signs of wear, not on the points, as might be expected, but on the outside. There is no chance of mistaking these prongs for feet, however, because in the case of the plain cones which have been found attached to the incensario this would necessitate inverting the effigy head on the body. The effigy cones discussed earlier in this paper have not been found attached to any Kaminaljuyu vessel, with the exception of one doubtful Las Charcas fragment (Fig. 97.5, caption) but, besides the fact that their close similarity to the plain cones leads us to suspect that they occupied the same position, the location of the worn surface makes their orientation as feet impossible, as in that case the wear would have been on the tips of the prongs; furthermore the effigy heads would have been upside down. Their identification as prongs was confirmed by the specimen found near Chiquimulilla (Fig. 97.7a), whose prongs represent a crudely modeled, bearded individual in the same style and technique as those from Kaminaljuyu. The interior of the stand is not smoked. It might be thought that these objects with their cone-like projections served no more than a decorative function because their upper surface rarely, and their interior never, shows signs of burning. This is to be explained, I believe, by the suggestion that the burning of incense took place in a separate container, a special bowl supported by the prongs.

A somewhat similar situation in the case of certain types of incensarios from later horizons at Kaminaljuyu bears out this idea. These Classic period

97.8. Principal incensario types at Kaminaljuyu: (a) see Fig. 97.7a; (b) see Fig. 97.6c; (c) see Fig. 6b'; (d) Kidder, Jennings, and Shook 1946: fig. 201h; (e) fragmentary, Guatemala National Museum; (f) see Fig. 97.3c; (g) see Fig. 97.6a; (h) Kidder, Jennings, and Shook 1946: fig. 201g; (i) Kidder, Jennings, and Shook 1946: fig. 201e; (j) Kidder, Jennings, and Shook 1946: fig. 201a; (k) Kidder, Jennings, and Shook 1946: fig. 201b; (l) Kidder, Jennings, and Shook 1946: fig. 201j; (m) museum no. 4925; (n) museum no. 4900; (o) fragmentary, Guatemala National Museum.

examples, which must have originated elsewhere as they show no direct evolutionary connection with those of the Miraflores Phase, have a generally flaring-sided upper receptacle intensely fire-blackened, whereas the lower part consists of a high annular

base with no sign of burning. Only the inside of the so-called "grater" bowls, believed to have been the prong-supported vessels in which the actual burning was done, is smoked, whereat the "incensario" itself, being comparable to the high annular base of

the later examples, lacks this evidence. The concept of a high base or stand is apparently one of the basic principles in the construction of incensarios, for it gratifies the wish to lift the offering up and away from the earth.

Found in connection with incensarios of the Esperanza Phase at Kaminaljuyu (Kidder, Jennings, and Shook 1946:212, Fig. 90) are tall "smokestack" covers which allowed the escape of smoke during the burning of the incense. The "grater" bowls also had covers, I believe. Vessels of the same coarse, unslipped ware and bearing similar deep grooves on the interior surface have been found in the same deposits with the "grater" bowls. They lack the wide overhanging rim but have instead a vertical apron and loop handle (for proposed restoration see Fig. 97.6c, c'). This sort of vessel would fit neatly on the rim of the other, suggesting its use as a cover, the loop handle enabling it to be lifted to permit ventilation during the burning process. The interiors of both the postulated container and the cover are heavily smoked.

All this simply leads to the conclusion that only the bowl supported by the prongs was used for the actual burning of the incense. The large three-pronged "incensarios" served merely as an elaborate support for the bowl. It therefore seems advisable to distinguish them from true incense burners by referring to them as *incensario vessel supports*.

Turning from the significance of the prongs on these incensario vessel supports for a moment, I wish to say a few words concerning the bifurcated, "fish-tail" protuberance on the top and to the vertical side-flanges. The protuberance may have been primarily decorative or ceremonial rather than functional as not all incensarios and incensario vessel supports have it. It is present on the tops of certain of these vessels throughout the early Classic and Preclassic periods with only minor changes in shape and size. The vertical side flanges, in addition to any decorative or ceremonial function they might have had, would have

been convenient handles for lifting and moving these vessels, which were frequently of considerable size. Their appearance in later times on smaller incensarios could indicate a religious significance or simply decorative conservatism. (For further information concerning flanged incense burners see Kidder, Jennings, and Shook 1946:213; Boggs 1949).

In concluding this section on the probable function and methods of use of the incensario vessel supports attention should be called to a possibly late type reported from the Motagua Valley of Guatemala (Smith and Kidder 1943:143, Fig. 22a, f), where two specimens, similar in many respects to the three-pronged variety found at Kaminaljuyu but much smaller, were found at San Agustín Acasaguastlan. Unfortunately the lower parts of these examples are missing, which makes it impossible to tell whether or not they had vertical flanges. Both have the bifurcated protuberance. Neither the prongs nor such parts of the bodies as remain are smoked, which indicates that, in spite of their small size, they presumably could have been used only as supports for the actual incensario vessel. Although one came to light in a Late Classic (Magdalena Phase) tomb and the other in a deposit containing sherds of the same period, the fragmentary nature of both makes it possible that they date from earlier times.

I wish to express my sincere thanks to Dr. Paul Fejos, Director of Research of the Viking Fund, and to Dr. A. V. Kidder, Chairman of the Division of Historical Research of the Carnegie Institution of Washington, for making possible this opportunity for further study in the Maya area. I also wish to thank the staffs of the Carnegie Institution and the Museo Nacional for their co-operation and help. Special acknowledgment goes to Mr. E. M. Shook, who supplied much of the information on the Las Charcas and Sacatepequez phases and permitted the description and illustration of some of his unpublished material, and to Sr. José Antonio Oliveros, who did the drawings for this paper.

GUATEMALA CITY

A Polychrome Maya Plate from Quintana Roo

Frans Blom

In a private collection in Oaxaca City is a Maya plate which probably is one of the most magnificent pieces of Maya ceramics and certainly one of the most intriguing (Fig. 98.1a). It was found in Quintana Roo, Mexico, not far from Chetumal Bay. I am much indebted to the owners for permission to reproduce it; it was first called to my attention by Mr. Frederick A. Peterson.

The plate measures 44 cm in diameter. Its surface is divided into two fields of equal size, the upper of which is covered with a multitude of figures and scrolls painted in black and brown with occasional red dots on an orange slip. The base is flat, the low sides are curved. The exterior of the base is slipped reddish orange, somewhat redder than the interior.

The center of the scene is occupied by a bird, which I shall discuss later, flanked by two seated men, each holding a blowgun. So far as is known, this is the only representation of users of blowguns in Maya art, in spite of the fact that the *Popol Vuh* constantly refers to this weapon. The black spots on the blow gunners' bodies indicate that the men are dead. Note the sights on the guns, I have made a quick but unsuccessful search of the *Popol Vuh* to find a passage which would describe this scene.

The strange bird, the Moan, sometimes with a human head and sometimes with a bird head, is quite frequent in Maya art. It appears at least three times at Palenque, once at Tikal, and at Tonina the stucco relief over a temple door, described by Stephens, shows this bird from the front (Figs. 98.1,11; 98.2a, b, a). It is also depicted as a clay whistle which was

98.1. Polychrome Maya plate from Quintana Roo: (a) polychrome plate, with representations of blowgun users; (b) stucco design, the Palace, Palenque, after Maudslay (1889–1902); (c) pottery figurine whistle, Tonina.

98.2. Representations of serpent-birds: (a) Temples of Cross and Foliated Cross, Palenque; after Maudslay (1889–1902); (b) wooden lintel, Tika1; after Maudslay (1889–1902); (c) detail of pottery figurine whistle (Fig. 98.2f); (d) stucco design over sanctuary, Structure A, Tonina.

found in a milpa at the foot of the slope where Tonina stands and which was given to me some years ago but is now in the Museo Nacional in Mexico City (Figs. 98.1c; 98.2c, j. Further search would no doubt reveal more representations.

In the plate illustrated here, the bird sits on the head of the earth monster, shown in profile. The out-

standing characteristic of this bird is its wing, part of which shows a serpent head in profile. Whatever head the bird may have, the serpent-head wings are always shown.

The lower half of the plate has a border of hieroglyphs along its edge. I like to imagine that they are a quotation from the *Popol Vuh*.

SAN CRISTOBAL LAS CASAS, CHIAPAS

"Olmec" Pictographs in the Las Victorias Group, Chalchuapa Archaeological Zone, El Salvador

Stanley H. Boggs

During a rather hurried reconnaissance of the Chalchuapa Archaeological Zone in 1942, a large, irregularly shaped boulder, decorated on four surfaces with incised human figures, was found in the Las Victorias coffee plantation about 2 km east of the city of Chalchuapa. At that time, I prepared a brief note of this discovery which was published in 1944 by Longyear (1944:17). No photographs of the stone accompanied the text, and the only conclusions then reached were that "the style of carving is very different from that usually found in El Salvador and may relate to the technique and time of the Tazumal stela."

The subsequent comparison of photographs of the Las Victorias monument with illustrations of bas-relief figures in the north and south ends of altar 5 at La Venta, Mexico (Stirling 1943, Pl. 41), has led me to believe that stylistically these carvings may be related and are presumably "Olmec"-inspired.

LAS VICTORIAS GROUP

The Las Victorias group of ruins in the Chalchuapa Zone has been very badly damaged as a result of long-continued cultivation of the soil scantily covering the remains. At present, the original nature and extent of the group is uncertain, owing both to this physical deterioration of the ancient constructions as well as to the fact that an extensive coffee finca, which now covers virtually the entire area, conceals whatever vestiges remain. The soil here is generally shallow, large outcrops of cracked and fissured stones of volcanic origin are visible at many points, and hundreds of boulders of the same material litter

the surface. The monument here discussed differed from scores of other surface stones only in its possession of carvings.

So far as I have been able to determine, this site contains no constructions comparable with those of the principal groups of the zone: remnants yet visible include low platforms and lines of stones, probably what is left of house mounds or foundations. No mound exceeding 1 m in height has yet been reported within Las Victorias group, nor indeed within 1 km of the stone monument.

THE LAS VICTORIAS MONUMENT

This monument consists of a large lava boulder of irregular form, decorated on each of four relatively flat surfaces with one incised or very low relief carving of a human, supposedly male, figure, three of which are portrayed standing or walking and one seated. There is no clear evidence of any special effort by the sculptor to prepare the surface of this stone; the figures were carved with little apparent regard to minor irregularities of the surface.

The stone itself is very hard, fine grained, grayish brown to gray; it shows many small air holes and probably relates to basalt. Its apex reaches 1.56 m above present soil surface. Some casual excavations around its base by finca employees prove that it extends but a short distance underground.

Since the carvings were adapted to the available rock surfaces and the entire stone has been turned slightly since 1943, probably during the aforementioned excavations, nothing can be said of the original

orientation. Roughly speaking, Figure A appears on the west surface, B on the south, C on the east, and D on the north (Fig. 99.1).

Figure A. Erect, probably walking, human figure, the body depicted in approximately three-quarters view but with face in profile and directed south. The left arm extends downward and away from the shoulder; the right arm, bent at the elbow, presses a bundle of some kind against the body.

Dress details are very sparsely indicated: a round pendant over the breast, a headdress of some soft (?) material which flows down over the sides and rear of the head, perhaps a jacket-like garment (more likely a poor drawing of the trunk), and a flap (of breech-clout or kilt?) which hangs behind the body to the knees. The upper part of the head covering has been broken off in fairly recent times, and the left hand and foot are missing.

The face is poorly sketched but its principal features are essentially similar to the corresponding elements of Figure C.

Figure B. Erect, probably walking, human figure in three quarters view, and face in profile and directed more or less east. The right arm holds a staff vertically and the left extends downward in front of the body. This figure stands on a more or less flat (platform?) surface, below which are toothed supports. Its staff suggests a thick pole over which a carved club-head has been slipped to serve as a weapon.

A helmet with a shoulder-length flap and a knob-like top covers the head. Suspended from the neck and resting on the breast is a large, more or less oval, pendant. Several horizontal lines about the waist seem to depict a broad belt composed of several bands or folds, while below, front and rear, vertical lines sketch the flaps of a breech-clout or "kilt." In the background, a generally rectangular area outlined from the height of the shoulders to below the knees may have been intended to signify a cloak.

Facial features, with the exception of the commonly pointed chin, differ considerably from those of other figures on this monument. The nose is pointed and rather aquiline, the sketchily drawn lips seem thinner than those of A and C, and the eye is a mere slit. The right ear is so clearly drawn that one might suspect that shoulder-length hair, rather than a helmet, is portrayed as covering the head. The expression of this face seems less dour than that of the other figures.

Figure C. Seated human figure in full face with head in profile, turned to its right facing south. The right arm rests on the right leg, hand on knee. The

left is bent at the elbow to grasp a rather elaborate staff or club. Damage to the stone after completion of the design has erased the upper portion of the headdress, the tip of the staff, and the lower half of the right leg.

The left leg is bent at the knee, suggesting a cross-legged, seated posture.

The staff generally resembles those of B and D, but its lower portion is much more detailed and appears to involve a bulging bundle of rods (?) with a glyph-like element superimposed. A strap-like object, broken at its outer extremity, separates the club head from the staff portion. The proportions of this staff or club would seem to imply that its employment was symbolical rather than utilitarian.

The headdress apparently consisted of at least three elements: a forward-projecting, stiff band or circlet slightly above or resting on the brow and turned upward at its outermost projection, a helmet-like peak, and a heavy, complicated covering of parts of the sides and rear of the head. This last covered the ears.

A broad flap or 'kilt,' probably the front portion of a breech-clout, hangs vertically from the waist. A narrow strap, suspended-vertically from the right shoulder, passes over the right groin. A similar band crosses over this at right angles, at the height of a large pendant or pectoral of cartouche form. Whether the pendant was attached to this second strap or, more likely, suspended from a third which encircled the neck of this figure is not clearly shown. The harness-like arrangement of these three straps, however, leads me to believe that the first two at least were parts of the dress and may have been functional, whereas the third was intended to delineate a necklace from which the ornamental pendant is suspended.

The facial features resemble rather closely in details those of A, but are here more elaborately drawn. The nose is concave, with a thick tip and widespread alae, perhaps rather "negroid." The down-turned, fairly thick lips and the heavy, jutting chin impart a somewhat grim expression to this countenance. The heavy-lidded eye seems to be closed (?).

The overall proportions of this figure are slightly greater than those of B and approximately double those of A and D.

Figure D. Erect, probably walking, human figure in three-quarters view, head in profile, facing east, and, like A, more schematically depicted than either B or C. the right arm, of which the lower third is missing, extends almost horizontally in front of the body; the left is bent at the elbow to grasp a long club-like staff with a sharp tip.

99.1. Monument 1, Las Victorias Group: (a-d) pictographs on Monument 1, Las Victorian Group; (e) Monument 1, showing B and C chalked.

Virtually no details of dress can be detected save a beaked, hat-like head-covering or helmet. Some cryptic lines about the base of the staff, a curve on

the left thigh and a bulge at the waist, may refer to some covering of the midsection, though this is questionable. The first suggest, from their position only,

fingers of the left hand closed around the base of the club. Of ornamentation, only a large round pendant resting on the breast can be discerned.

Drawing of the face is also very sketchy. The nose is virtually round in profile and seems to show broad alae. The round, jutting chin and down-turned lips reflect such features better portrayed in A and C. A curved line immediately behind the jaw may sketch the lobe of the left ear.

REMARKS

The pictorial significance of Las Victorian monument may be impossible to interpret. A rather obvious, very possibly erroneous, guess is that the four figures are centered on C, since that is the most elaborately drawn and the only seated member of tile group. From this point of view, accepting all as the component parts of one (court?) scene, B and D, which face around the stone toward C and carry simple clubs, may personify priestly subordinates or military guards of the chief, and D a petitioner or tribute-bearer.

On the other hand, readily observable individual differences in attitude, scale, details of dress and of facial features intimate that A and D may not have been carved at the same time as B and C, and were almost certainly not the work of the same sculptor. In some degree, the former seem inferior imitations of the latter. However, B and C differ markedly one from the other in nearly all respects save style and execution, a fact which inclines me to believe that two sculptors were employed, each responsible for one pair of figures, although the pictographs may have been completed at approximately the same time.

Whatever the idea and purpose of these carvings may have been, one interest they possess for the

archaeologist stems from their possible relationship with La Venta bas-reliefs. Obvious restrictions on any attempted comparison are the superior technique, greater elaboration, and finer execution of the La Venta figures as well as the difference in subject matter. However, after taking into account these variations and the considerable distance between the two sites, there remain surprising similarities in artistic style and in several specific details. For example, the idea back of the strange "hats" or helmets, as well as certain details of these objects themselves, are very distinctive and characteristic of figures on both monuments. Again, the lips, noses, eyes, and chins of all show many points of correspondence. Whether either or both the La Venta and the Las Victorian monuments were carved by "Olmec" sculptors may be queried, but that both are expressions of basically the same artistic tradition seems highly probable.

Turning to the date of the Las Victorian monument, we find that virtually no evidence exists in El Salvador on this point. No careful excavation has been attempted in this part of the Chalchuapa Zone, and surface sherds indicate a very long occupation of the area, from perhaps before the time of Christ to the present. Stirling assigns the major stone monuments at Tres Zapotes to the Lower and Lower Middle periods established there and postulates an early, apparently roughly similar, time for the La Venta monuments. If we accept his suggestion, the temporal position of this particular style of sculpture would appear to refer to Preclassic centuries of the Christian era and, at a guess, the Las Victorian pictographs may be no later than the fifth century. Whether a major time lag is involved between the execution of the Mexican carvings and that of their Salvadoran comparatives is problematical in view of the lack of contributory ceramic evidence associated with the monuments themselves.

A Group of Jointed Figurines in the Guatemala National Museum

Stephan F. de Borhegyi

A small group of "Archaic" figurines, thought to be of interest to students of Middle American archaeology, came to light during organization of the large study collection of the Guatemala National Museum. This project is being made possible by a fellowship granted by the Bollingen Foundation of New York to the writer, who wishes to express his indebtedness to this institution, as well as to Dr. Heinrich Berlin for helpful suggestions and to Sr. Antonio Oliveros for careful drawings. A description of two figurines from Kaminaljuyu, on the outskirts of Guatemala City, and one from the ruins of Tazumal in El Salvador follows.

Female figurine torso (Fig. 100.1a-e). Yellowish white, finely polished, Miraflores ware with a grayish yellow paste containing particles of white volcanic ash. Both head and legs of the figurine are now broken off. Creases and folds in the solid, carefully modeled 'body are indicated by pre-slip perforations and incisions. The under part of each shoulder forms a smooth-edged cup, from the center of which a hole runs to the back of the neck. The holes, made by a sharply pointed instrument, are indicated in Figure 100.1c, d by parallel dotted lines.

Height of torso: 9 cm. Diameter of shoulder cups: 1.5 cm. Provenience: Kaminaljuyu surface find near the area called Arenal. Guatemala National Museum No. 2357a. Chronological position: Late Preclassic, Miraflores phase.

Small female figurine torso (Fig. 100.1f, g). Weathered, yellowish white, Miraflores ware with yellow-

ish brown paste containing volcanic ash and mica temper. The head and legs are missing. The solid, carefully modeled specimen represents a pregnant woman in sitting position. Each shoulder forms a smooth-edged cup although, unlike those of Figure 100.1, they do not have the transverse hole from the center of the cup to the back of the neck. How the arms were attached is problematical.

Height of torso: 3 cm. Diameter of shoulder cups: 7 mm. Provenience: Kaminaljuyu surface find. Guatemala National Museum No. 2357b. Chronological position: Late Preclassic, Miraflores phase.

Female figurine torso (Fig. 100.2a, b). Yellowish white ware with grayish yellow paste containing particles of white volcanic ash. The solid specimen is very weathered and consists only of the right upper part of the trunk. The right shoulder forms a smooth-edged cup perforated in the same manner as in Figure 100.1a-e.

Height of torso: 6.3 cm. Diameter of shoulder cup: 1.4 cm. Provenience: Tazumal, near Chalchuapa, El Salvador. Surface find. Guatemala National Museum Lot No. S-1.+ Chronological position: probably Late Preclassic.

This small group of figurines seems to bear a close relationship to the finely finished yellowish white figurine arm from a Miraflores deposit at Kaminaljuyu illustrated by Kidder (Fig. 92.5e) and reproduced here as Figure 100.2c, d (Museum No. 2317). At the time of its discovery, this specimen was the first evidence that jointed figurines were made

a

b

c

d

e

f

g

h

100.1. Jointed figurines in the Guatemala National Museum.

by Archaic people in Guatemala. It was thought that the applied perforated boss must have, to quote Kidder, "fitted into a cup in the edge of a flattish

body that was perforated front-to-back." A careful re-examination of this specimen has revealed that, rather than being a leg, as originally thought, it is a

a

b

c

d

e

100.2. Jointed figurines in the Guatemala National Museum.

a

b

100.3. Jointed figurines in the Guatemala National Museum.

left arm, the fingers of which, as well as the greater part of the palm, having been broken off. A restoration of the hand is indicated by the dotted line in Figure 100.2d.

I am of opinion that the shoulder treatment of the figurine torsos here considered may well constitute the cup postulated by Kidder. Somewhat smaller bosses than that of Figure 100.2c, d would fit neatly into the shoulder cups of the figurines just described. Except in the case of Figure 100.1f, g a cord could be knotted through the perforated boss of each arm and passed through the transverse holes to meet at the back of the neck. In this way the arms are so attached that they could be lifted singly or in unison by pulling upon the cord, a method similar to that used to work marionettes (Fig. 100.3a). So much we know of the appearance and attachment of the arms but as for the legs, little is known. Judging from the Mexican examples, such as illustrated by Spinden from Teotihuacan (1922, Fig. 57) and here reproduced as Figure 100.3b one would expect the legs as well as

the arms to be jointed, but the Guatemala specimens suggest that they formed parts of the solid body, as indicated in Figure 100.3a.

Information as to the occurrence, other than at Kaminaljuyu, of this type of jointed-arm figurine is lacking, being limited so far to one specimen from Tazumal on the western border of El Salvador. For further data on relations between Kaminaljuyu and Tazumal, see S. H. Boggs (1944). In a letter of October 24, 1950, Boggs kindly informed me that the jointed-arm figurine type is at Tazumal not uncommon, though statistically it occurs in small percentages. Further details can therefore be expected in his forthcoming publication on the excavations at Tazumal.

Perhaps one of the most interesting points in connection with these Late Preclassic jointed-arm female figurines from Kaminaljuyu is that, although considerably earlier than the apparently sexless specimens from Mexico, they involve a mechanical concept both more sophisticated and more complex.

In the case of the Mexican examples the top of each arm and leg is perforated instead of having a boss. A cord was passed through a transverse hole from shoulder to shoulder and from hip to hip through the solid, usually flat, triangular body as seen in Figure 3,b. They are common throughout the Classic period (Teotihuacan III and Upper Tres Zapotes), and are reported from Teotihuacan (Gamio 1922:1, Pl. 87a, b; Spinden 1922: 178, Fig. 57), San Miguel Amantla and Santiago Ahuizotla (Seler 1915c:473, Pl. XXXII, Fig. 2), Jalapazco (Seler 1915c, Fig. 1), Huamantla (Seler 1915c, Pl. XIX), Tres Zapotes (Drucker 1943b:121, 132, Pls. 41,w; 47,1; Weiant 1943:116, 123, 128; Pl. 61, first row), near San Andres Tuxtla (Seler-Sachs 1922:24, Pl. 10; Valenzuela 1945a:88, Fig. 5; 1945b), from the Zempoala region (Garcia Payon 1950:102, Pl. 16, Fig. 6), from the Pavon site near Tampico (Ekholm 1945:457, Fig. 42k), Tajumulco (Dutton and Hobbs 1943).

These doll-like figurines with their movable joints, although of two distinct types, are possibly of similar concept; their wide geographical distribution and long duration argue for their considerable importance. To just what important function these pre-Columbian "dolls" may be assigned is unknown. What seems to be most likely, as already suggested by Kidder (p. 17), is that they may have served some brief but unknown purpose in ceremonies and were later given as toys, like the Hopi katchinas, to amuse the children and, what is worse, confound such playful adults as archaeologists.

Since this paper was submitted, Note 95 in this series has been published. In it Kidder illustrates another jointed arm from Kaminaljuyu with perforated and longitudinally grooved boss, which I here reproduce as Figure 100.2e. This specimen is also of finely finished Miraflores white ware.

A Study of Three-Pronged Incense Burners From Guatemala and Adjacent Areas

Stephan F. de Borhegyi

Since the recent discussion (Note 97) of a group of cone-shaped effigy heads and three-pronged incense burners from the Preclassic period at Kaminaljuyu, the large archaeological site just outside Guatemala City, some interesting new specimens have come to light. Their study has brought about new concepts and filled several gaps unavoidably left open in the earlier report, as well as necessitated some slight alterations in the theories previously advanced. This study was made possible by a grant-in-aid from the Bollingen Foundation of New York, to which institution I am greatly indebted.

Thanks go to Dr. A. V. Kidder for unfailing help and encouragement and to E. M. Shook and Heinrich Berlin for many helpful suggestions. The drawings were made by Sr. Antonio Oliveras of the Guatemala National Museum, photographs by Dr. Kidder (Figs. 101.1–101.3; 101.4a) and by Sr. Eugenio Escaler (Figs. 101.4b–6).

The materials are in the Guatemala National Museum and in private collections in Guatemala. Little is known of their provenience or age. Many have passed from hand to hand, thereby losing all identity, and it is only recently that, in the organization of the collections of the museum, they have been recognized as members of this interesting type of incense burner.

DESCRIPTION OF MATERIAL

1. Large, cylindrical, three-pronged incense burner (Fig. 101.1). One badly damaged solid prong remains,

the other two have been broken off but scars indicate their position and basal diameter (8 cm). The reddish brown ware is well smoothed but unpolished. The paste is also reddish brown and liberally sprinkled with particles of white temper, presumably volcanic ash. A grotesque, conventionalized jaguar face with open mouth is depicted below the upper jaw of another jaguar or possibly serpent. The solid snouts of both animals and their sharply filed teeth are applied to the front wall of the vessel. The incisors of the upper face are tau-shaped and the corresponding teeth of the lower face, although broken, appear to have been similar. The large oval eyes, eyebrows, and lips are well modeled, probably of applied fillets. In addition, the face of the serpent-like creature is adorned with 10 spherical buttons, four of which are applied to parts of the upper lip, one above each eyebrow, one on either side of the eyes, and one on either side of the projecting snout, possibly as a representation of nostrils. The side flanges (30 cm long and 5 mm thick) are also applied and are adorned with three larger, flat, appliqué buttons (5 cm in diam.) evenly spaced along the length of each flange. Immediately behind each flange a round vent (7 cm in diam.) has been cut in the vessel wall and the edges carefully smoothed. Light vertical raking is visible on the back; horizontal striations encircle the interior.

Covering the entire piece is a red slip; traces of a calcareous white wash are present on the eyes and teeth of both animals, the prongs, the bulging rim around the base, the top, and the less carefully smoothed posterior half. The short, blunt, beardlike

101.1. Three-pronged incense burners from Guatemala.

protuberance of the jaguar face bears traces of thin yellow paint. Between the two frontal prongs there may have been a connecting ridge.

The flat top and the solid stump of the one remaining prong are fire-blackened. The well-smoothed interior shows no sign of fire or smoke.

Dimensions: ht. (without prongs) 38, basal diam. 32, top diam. 18.5 cm. Provenience: Hartwell

M. Webb collection, Guatemala National Museum, private coll. no. 9; believed to be from Kaminaljuyu. Comparative material: Several solid fragments of snouts, similar to that of the jaguar face, were found by Carnegie Institution at Kaminaljuyu. Apparently, these had been broken from similar incense burners. Chronological position: probably Late Preclassic, Miraflores phase.

2. Fragments of a cylindrical three-pronged incense burner (Fig. 101.2). The ware is coarse and reddish brown; paste thickly sown with white crystalline particles. A grotesque, conventionalized jaguar face with open mouth is depicted on the front wall. The teeth, fangs, eyes, tongue, ears, and nose are applied. A vague indication of a vertical side flange is present on the remaining portion of the left wall. The frontal solid prongs (basal diam. 3 cm) are broken; the rear part of the rim and the third prong are missing but the three were undoubtedly placed in the usual triangular formation as on another fragment with the same top diameter in which the scars are clearly visible (Fig. 101.2b, c): A low ridge (6.5 cm long) connects the two frontal prongs on each specimen.

Faint traces of a thin white wash are present on the prongs and the slightly convex top. These areas are heavily fire-blackened; no evidence of smudging on the interior.

Dimensions: ht. (without prongs) 7, top diam. both specimens 15 cm. Provenience: Both in Guatemala National Museum (Fig. 101.2a; no. 3487). They were recovered at Kaminaljuyu by Carnegie Institution in 1949 from a pit in the northern part of the area called Arenal. Chronological position: Late Preclassic (possibly Arenal subphase of Miraflores).

3. Cylindrical, three-pronged incense burner (Fig. 101.3a, a', a''). All three prongs, presumably solid, are broken off; the remaining scars indicate a basal diameter of 5 cm. The ware is coarse, unslipped, unpolished, reddish brown; paste slightly darker, tempered with mica and white crystalline particles. A grotesque, probably human, face with open mouth, arched nose, and flat, protruding cheeks, lip, and ears, is depicted on the front wall. All features are applied. There are two plain, vertical flanges, 16.5 cm long, 7 mm thick; a vent, 2.5 cm in diameter, behind each. Between the frontal prongs is a connecting ridge 6.5 cm long.

Remains of a thin white wash around the face and on the front base suggest that the entire front was once so covered. No signs of a wash are present on the rear but that surface has been lightly raked as in Figure 1. The top is fire blackened but not the interior.

Dimensions: ht. (without prongs) 24, basal diam 15 cm. Provenience: Guatemala National Museum, no. 7336; believed to have come from Kaminaljuyu. Chronological position: probably Late Preclassic, Miraflores phase.

4. Fragment of cylindrical three-pronged incense burner (Fig. 101.3b, b', b''). All three prongs, presum-

101.2. Three-pronged incense burners from Guatemala.

ably solid, broken off but scars indicate a basal diameter of 1.4 cm. The ware is coarse, unclipped and slightly smoothed but unpolished, reddish brown with slightly darker paste tempered with pumice and mica. A grotesque, probably human, face with wide-open mouth is on the front wall, the effect being that of a Greek mask of tragedy. The four pointed teeth (lower left now broken) and the button nose are applied. Lips, eyes, forehead pendant, and eyebrows may have been applied or possibly modeled. Although not connecting there, a ridge 5 cm long lies between the frontal prongs. Remains of a white wash are visible around the lips, nose, and forehead pendant. Top but not interior fire-blackened. The specimen is too fragmentary to say whether or not it had vertical side flanges.

Dimensions: ht. (without prongs) 17, top diam. 16 cm. Provenience: Guatemala National Museum, no. 4384; believed to be from one of the archaeological sites at Asuncion Mita, Dept. of Jutiapa, Guatemala. My only source of information concerning provenience was the old museum catalog (no.

2298), which in many cases has proved inaccurate. I believe the specimen is of Late Preclassic date and probably comes from Kaminaljuyu, because similar fragments occur there in Miraflores deposits. Comparative material: sherds from incense burners with similar paste and bearing modeled or applied eyes or eyebrows, frequently with traces of a white or yellowish wash, were found at Kaminaljuyu near Mound E-III-3 by Carnegie Institution: chronological position: probably Late Preclassic.

5. Top fragment of large three-pronged incense burner (Fig. 101.4a, a'). The ware is unclipped, unpolished, reddish brown; paste darker, thickly sown with white particles. One complete and one fragmentary large hollow prong, 13 cm in basal diam., remain; a vent, 2.5 cm in diameter, at the base of each. Between the frontal prongs is the remnant of a connecting ridge 3.6 cm high. A vestige of a vertical flange is present on either side of the vessel. A vent, probably round, has been cut in each of the two side walls and the edges smoothed. Twisted appliqué fillets and spherical buttons are applied to a flat scroll formerly attached in some manner to the front. Unfortunately the fragmentary condition of the specimen makes the restoration questionable. The top and prongs are covered with a thin white wash and are fire blackened. The rough interior shows no sign of smudging.

Dimensions: ht. of prong 28, top diam. ca. 47 cm. Provenience: Guatemala National Museum, lot no. C-42; from bottom of deep barranca northeast of Mound E-II-1, Kaminaljuyu; Carnegie Institution, 1948. Association: the same lot contains several fragments of a fire-blackened, deeply scored, coarse ware incense burner cover, believed to have been used in connection with this specimen. The theory that the prongs of the three-pronged incense burner supported such a cover was discussed at length in Note 97 (Fig. 97.6c): These covers were formerly referred to as "heavily scored grater bowls" (Note 89; Shook 1951). Fragments of fine incised Miraflores black-brown ware, white ware, and red ware "flower-pots" are also numerous in the lot. Chronological position: Late Preclassic, possibly Verbena subphase of Miraflores.

6. Top fragment of three-pronged incense burner (Fig. 101.4b, b'). The fragment bears one hollow prong, with a vent 2.5 cm in diameter at the base. The ware is light pinkish orange, considerably weathered; paste slightly darker, contains particles of white temper. Parallel striations encircle the slightly concave top. Neither side remains to indicate the presence or lack of side flanges. Below the rim is

101.3. Three-pronged incense burners from Guatemala.

a section of a smooth-edged triangular opening in the wall, presumably decorative. No trace of slip or wash, probably due to weathering. Fire-blackening on the top but not in the interior.

Dimensions: ht. of prong 13, top diam. ca. 32 cm. Provenience: Guatemala National Museum, no. 4203. Found by Gustav Strömsvik in the main plaza of Quirigua during work by Carnegie Institution in 1934. At the same time, similar but more fragmentary pieces of broken, hollow prongs were found in Pit 7 in the cobble pavement of the same plaza. Associated material: Weathered base sherds of round,

101.4. Three-pronged incense burners from Guatemala.

hollow-footed tripod vessels of Late Classic type and Morocco red-on-orange ware flaring-sided bowls (Copador type). The red paint of the latter contains specular hematite. Also in association were heavily fire-blackened sherds of deeply scored incense burner covers of the same ware and paste as the incense burner. Comparative material: The effigy-pronged incense burner from Chiquimulilla, Dept. Santa Rosa, Guatemala (Fig. 97.7; Kidder, Jennings, Shook 1946, Fig. 202.c, shown inverted), has similar triangular openings in the vessel wall. Chronological position: probably late Classic.

7. Two effigy prongs from three-pronged incense burners (Fig. 101.5a, b). (a) Hollow effigy prong depicting the wrinkled face and stooped Figure of an old man. Only a small section of the rim still adheres to the prong. An unpolished yellow-ocher slip is applied to a reddish brown paste containing particles of white temper. The features, earrings, and "peaked cap" headdress of the effigy are moldmade but the arms and legs are modeled; fingers and toes are indicated by crude, preslip, incisions. At the middle, below a horizontal groove suggestive of a belt, is a vent 7 mm. in diameter; a second vent is in the rounded top of the prong. The feet of the old man, as well as the prong itself, rest on the gently outcurving rim of the incense burner. Below the rim is a carelessly painted, dark red horizontal line, 3.5 cm wide. Parallel to this and 1 cm below is a finger-indented fillet. To judge from the angle of breakage, the top of the specimen must have been slightly convex. The back of the prong is lightly smudged.

Dimensions: ht. of prong 18.5, basal diam. of prong 8.5 cm. Provenience: Dieseldorff Collection, Guatemala National Museum, no. 5796; provenience unknown. Comparative material: A similar moldmade effigy prong from an incense burner was exhibited in September 1950, at the Honduran Cultural Exposition in Guatemala City. It bears the face of an old man with a "colonial cocked hat" headdress. The ware is unpolished grayish ocher and the paste contains particles of white temper. As in most prongs, the top is slightly worn on the outside and a vent, 2 cm in diameter, is at the exterior base. In addition, there is a narrow slit under the chin of the effigy. The exterior wall of the stand has been raked vertically. The specimen is said to be from the Sula Valley in northwestern Honduras and is in the private collection of the Escuela de Belles Artes of Tegucigalpa. Unfortunately no photograph was taken. Another similar group of moldmade effigy prongs from three-pronged incense burners has been reported from Travesia and San Pedro Sula, Honduras, although they were described as "rising inner

handles from large vessels" (Stone 1941:82, Figs. 93; 94j, o). Chronological position: probably Late Classic or Early Postclassic.

(b) Hollow effigy prong depicting moldmade animal, probably pisote (Fig. 101.4c, c'). The animal is squatting on the flat rim of an incense burner fragment with what appears to be a scarf knotted around its neck. The ware is moderately well polished and pinkish cinnamon over a very sparingly tempered, slightly darker paste. The prong and the remains of the rim are well fire-blackened; interior wall unsmudged.

Dimensions: ht. of prong 8.5, basal diam. of prong ca. 6 cm. Provenience: Dieseldorff Collection, Guatemala National Museum, no. 5924; provenience unknown. Chronological position: probably Late Classic or Early Postclassic.

8. Incense burner with three flattish, bowed columns supporting a cover (Fig. 101.6). Superficially polished, reddish brown ware; darker brown paste containing particles of white temper. No trace of paint or wash. The specimen consists of two major parts: bell-shaped base with three vertical, slightly bowed columns; and an attached hemispherical cover resembling a sailor's cap. Two round vents 3 cm in diameter have been punched in the wall on either side. The exterior of the flaring rim and the concave interior of the cover are scored with deep parallel and crisscross lines, executed while the clay was still in the leather-hard stage, the edges being jagged and elevated above the general surface. On the apex of the cover a modeled animal head has been applied. A smoke outlet runs from the interior of the cover through the neck and out the mouth. The animal appears to be a jaguar. Both the eyes and ears are applied. The mouth is badly damaged but at one time sharp teeth were represented by deep incisions. The interior of the cover, the smoke outlet, the flattish columns, and the slightly convex upper surface of the base are all heavily fire-blackened. The interior of the bell shaped base bears no sign of smoke or burning.

Dimensions: total ht. 33, basal diam. 20, top diam. 24 cm. Provenience: Private collection of Sr. Juan Jose Pellecer, Antigua, Guatemala; provenience unknown. Chronological position: unknown. Comparative material: a similar specimen was noted by E. M. Shook in the private collection of Sr. Jose Llarena, Antigua. Of similar ware and paste but of much finer workmanship than the foregoing, it is somewhat taller (total ht. 38, basal diam. 18 cm). A finger-indented fillet encircles the base. The animal head on the cover also suggests a jaguar but is more carefully modeled and in addition has an outstretched tongue.

101.6. Three-pronged incense burners from Guatemala.

There are traces of white wash on the stand. Exactly the same areas show smoking as on the specimen here illustrated. Provenience and age unknown.

A deeply scored fragmentary incense burner cover with loop handle of the type formerly called "grater bowl" is illustrated here (Fig. 101.5c-f) for comparison with the cover of the Antigua specimen (Fig. 101.6). It was found in 1947 in the Santa Clara district of Guatemala City (lot no. C-27) associated with Las Charcas material (diam. 29 cm). The interior of the cover is heavily fire-blackened as is the one illustrated in Figure 101.6. An interesting piece of Nicoya polychrome ware from the Nicoya Peninsula of Costa Rica bears a vague but nevertheless striking resemblance to the Antigua specimens. The annular base of the vessel is surmounted by three solid, slightly bowed columns which support a shallow bowl with scalloped rim. The base has four triangular openings similar in treatment to Figure 101.6 and to Figure 97.7. Unfortunately, the photograph does not show clearly the grotesque face with large round eyes depicted on the body wall, and can therefore not be compared with the specimens illustrated and discussed in this paper (Lothrop 1926:129, Fig. 32).

9. Not illustrated in this paper but present among the sherd lots in the Guatemala National Museum collected by Carnegie Institution from various locations at Kaminaljuyu, are a great number of the solid or hollow prongs from three pronged incense burners as well as fragments of the deeply scored covers. Although all are very fragmentary, a considerable number bore loop handles such as illustrated in Figure 101.5c, e. Some 63 solid and 12 hollow prongs of the plain conical variety were assembled for study, besides 167 deeply scored cover fragments. Their abundance suggests a role of considerable importance at Preclassic Kaminaljuyu.

Dimensions: top diam. of incense burner 10-47, ht. of prongs 7-28, basal diam. of prongs 2-13 cm. Chronological position: early and Late Preclassic. Comparative material: Figures 101.2c; 101.4a, a'; 101.5c-l.

DISCUSSION

The specimens here described do not form a homogeneous group, nor are they from the same chronological horizon. The fact that all have three symmetrically placed prongs or columns, although these may be solid or hollow, plain or effigy, unites them and they are presumed to have served the same or a similar function, doubtless ceremonial.

In Note 97 I made a tentative reconstruction of the appearance and use of several three-pronged

incense burners from Kaminaljuyu similar to some of those here described. The discovery of the previously unknown Antigua incense burners (Fig. 97.6) necessitated certain changes in the theory previously advanced.

I had formerly supposed that the three prongs supported a deeply scored hemispherical "grater bowl" with wide overhanging rim and that a similarly shaped and scored cover with center loop handle was placed on the rim of the bowl to form a closed chamber in which incense could have been burned (Fig. 97.6b, c). Following this line of reasoning, I tentatively designated these pronged specimens "three-pronged incensario supports."

The discovery of the two examples of the previously unknown Antigua type has thrown new light on the picture, for they seem to be the missing link obviously connecting the three-pronged incense burners with the deeply scored "grater bowls." It now appears that the hemispherical bowl had no place in the postulated reconstruction (Fig. 97.6c). Apparently only a cover rested on the outer tips of the prongs and the burning took place, not in a closed chamber formed by bowl and cover but on the top of the incense burner, thereby causing the blackening of the prongs anti top as well as the interior of the cover. The handle was used to remove the cover from, or return it to, the prongs but, in the specimens from Antigua, effigy heads with smoke outlets served as handles. Except for this difference, the attached covers of the Antigua specimens are identical to the deeply scored covers (cf. Figs. 97.6c, f; 97.5c, d).

The combination of deeply scored cover with three-pronged or three-columned stand, together with similarity in ware and paste, and both chronological and cultural association, makes fairly certain the connection of these objects throughout their history. Unfortunately, the Antigua specimens cannot be dated; it is therefore impossible to say whether this columned type represents a beginning, intermediate, or final stage in the development of the three-pronged incense burner.

Pending further information, my previous reconstruction should be ignored and the name "three-pronged incense burner supports" changed to "three-pronged incense burners supporting wide-brimmed, deeply scored covers with loop or effigy handles."

As stated above, the similarity in appearance and function of all these specimens unquestionably unites them, and the fact that they were surely incense burners presupposes their ceremonial character. It is not too difficult to believe that they pertained to a single religious cult or even were dedicated to the worship of one particular deity such as

the Kaminaljuyu rain god. The theory that some of the cone-shaped effigy prongs from three-pronged incense burners represent the Kaminaljuyu rain god was advanced in Note 97. Bearing out the idea that all pertained to a single cult are the many likenesses noted among the specimens, although several are widely separated in time and space. The following paragraphs indicate the common characteristics of most of the specimens described in this paper and in Note 97:

1. *Grotesque human face*, characteristically present on the hollow, effigy prongs of the Early Preclassic period (Figs. 97.5, 97.7), as well as on the front walls of the plain-pronged incense burners of the Late Preclassic period at Kaminaljuyu (Fig. 97.3; Figs. 97.6, 11; Fig. 97.8d). The face is usually represented with open mouth, often with sharp, filed teeth, outstretched tongue, beard, tusks, and fangs, and probably tear streaks (Fig. 97.5b, e, f; Kaminaljuyu rain god?). On the other hand, the Late Classic moldmade effigy prongs often depict an aged man with wrinkled face (Fig. 101.5a; Stone 1941, Fig. 93).

2. *Jaguars or serpent-like monsters*, present on the covers of the incense burners from Antigua (Fig. 101.6) and on the front walls of the Late Preclassic incense burners (Figs. 101.1, 2; Fig. 97.6b). They are found also on the large three-pronged stone altars from Kaminaljuyu which are believed to belong to the Late Preclassic period (Fig. 97.6a). The face is usually represented with open mouth, sharply filed and sometimes tau-shaped teeth, outstretched or bifurcated tongue, tusks, and fangs. (For possible connections between the tiger faced god and the Kaminaljuyu rain god see Note 97).

3. *Vertical side flanges*, common on specimens from the Late Preclassic (Figs. 101.1–101.4; Fig. 97.6b) but may have originated during the Early Preclassic period (Sacatepequez phase, Fig. 97.8c). They are also found on the stone altars (Fig. 97.6, 1).

4. *Bifurcated protuberance* applied to the front rim or between the frontal prongs, noted on two of the late Preclassic (Miraflores) specimens from Kaminaljuyu (Figs. 97.6b; 97.8d) and on two Late Classic (Magdalena) incense burners from San Agustín Acasaguastlan (Smith and Kidder 1943, Fig. 22a, f).

5. *Ridge connecting the frontal prongs*, common on Late Preclassic specimens (Figs. 101.2–101.4) as well as on the three pronged stone altars.

6. *Circular vent in the center of the top*, noted on Early Preclassic specimens. In one case a hole was punched completely through the top (Fig. 97.7); in another it consisted only of a deep circular indentation (Shook, MS. on Las Charcas material). It was also present on one Late Preclassic specimen (Fig. 97.6b).

7. *Triangular or rectangular openings in the vessel wall*, present on the walls of the Early Preclassic effigy-pronged incense burners (Fig. 97.7; Shook, MS.) as well as on the Late Classic plain-pronged specimen from Quirigua (Fig. 101.4b).

8. *Round or irregular opening on prong*, found on all plain or effigy hollow prongs. The opening generally takes the form of a mouth or a hole under the chin of the effigy, or a smooth edged vent at the base of the plain prongs. One specimen bears another hole at the top of the prong (Fig. 101.5a). As any hollow prong must have a vent to prevent cracking in firing, only the position and form of the vent are of significance.

9. *Wide-brimmed, deeply scored covers attached to or supported by the prongs*, attached to a three-columned, bell shaped base on the two specimens from Antigua (Fig. 101.6). It is presumed that a similar cover, but with loop—instead of effigy—handle, was used in connection with the three-pronged incense burners and was set on the prongs rather than permanently attached to them (Fig. 101.5c–e).

10. *White calcareous wash*, thin white (sometimes yellowish) coating applied to the majority of the incense burners examined.

11. *Thin red paint* seems to have been the only other pigment used. It was applied either as an overall covering or as geometric design elements. It is present on the Early Preclassic specimens (Fig. 97.7); Late Preclassic examples, including the stone altars (Fig. 101.1; Fig. 97.6a) and on those of the Late Classic period (Fig. 101.7a; Smith and Kidder 1943, Fig. 22a).

SUMMARY

In a summary of this study it seems desirable to classify the various types of incense burners and covers according to location and chronological period. Such a tentative classification, naturally limited to the information available and on hand at the moment (see chart), follows:

- (1) Three-pronged incense burners with handmade effigy prongs,
- (2) three-pronged incense burners with moldmade effigy prongs,
- (3) three-pronged incense burners with solid or hollow plain prongs,
- (4) three pronged incense burners with combined cover,
- (5) three-pronged stone altars.

Early Preclassic period (see chart), characterized by incense burners with three, hollow, modeled effigy prongs usually representing grotesque human faces, frequently bearded (Kaminaljuyu rain god?; Figs. 97.5b, d, 97.7). The wall is perforated with triangular or rectangular openings and is occasionally painted red. Deeply scored covers with loop handles were supported by the prongs. At the end of the period the solid and hollow plain prong seems to dominate and the vertical side flange appears (Shook, MS.). Probably there were no bifurcated protuberances or connecting ridges at this time. Distribution: Kaminaljuyu and Chiquimulilla (Dept. of Santa Rosa) in Guatemala.

Late Preclassic period, characterized by incense burners with hollow or solid, but plain, conical prongs. The three pronged stone altars from Kaminaljuyu should probably be assigned to this period. The stands usually have a bifurcated protuberance or a connecting ridge on the top. On the front wall there is generally a grotesque jaguar, serpent-like, or human face, usually with open mouth. The prongs supported an unattached deeply scored cover with loop handles. There is no evidence of either effigy prongs or triangular or rectangular openings. Distribution: Common at Kaminaljuyu, possibly indicating the strongest development of the complex at this site. One small rim fragment of a deeply scored cover was found by Wauchope (not illustrated) at Zaculpa in Group A of the Central Barranco and two at Chiche (Wauchope 1951a:139, Figs. 23a, f; 36h). Both sites are in the Dept. of Quiché, Guatemala. They may be from the early Balam phase which, according to Wauchope's new classification, is proto-Classic (Wauchope 1951b:242). Fragments of deeply scored incense burner covers are in the Museum collections from San Andrés Semetabaj (Dept. of Solola) and Salcája (Dept. of Quetzaltenango). Similar deeply scored covers were found in Period II deposits at Gualupita, Cuernavaca, Morelos, Mexico, by Vaillant although at the time they were reported as "graters" (Vaillant and Vaillant 1935:95–97, Fig. 28d). In a letter of October 6, 1950, Dr. Ekholm informed me that they are fire-blackened on all sur-

faces. Deeply scored covers were also reported from Yarumela, Honduras (Canby 1949).

Early Classic period. No type of three-pronged incense burner has thus far been encountered which could safely be assigned to this period. A specimen from Kaminaljuyu (Kidder Jennings, Shook 1946, Fig. 201h; Guatemala National Museum, no. 2422; Fig. 97.8d) was found in an Early Classic Esperanza mound but is now thought to be from a Late Preclassic horizon (verbal communication from Dr. Kidder). Some fragments of crude, deeply scored covers occurred in the Esperanza mounds at Kaminaljuyu but these lack the deep overhanging brim of the earlier type. Because of their position in the mound fill, which contained many Preclassic sherds, these are also possibly from the preceding period.

Late Classic period, characterized by solid or hollow plain, or hollow effigy-pronged incense burners. Bifurcated protuberances are present on two specimens from the Motagua Valley (Smith and Kidder 1943, Fig. 22a, f). Triangular openings were occasionally cut in the vessel wall (cf. Fig. 101.4b'), A thin red paint is present, usually in a horizontal band around the vessel (Fig. 101.7a; Smith and Kidder 1943., Fig. 22a). The effigy prongs and the faces on the wall represent such animals as the monkey (Smith and Kidder 1943, Fig. 22f) and the pisote (Fig. 101.7b); occasionally a wrinkled and stooped old man (Fig. 101.7a; Stone 1941, Fig. 93). The faces on the effigy prongs are often moldmade. The few specimens from this period are so fragmentary that it is unknown whether or not vertical side flanges were present (see Note 97). At Quirigua the Late Classic prongs were found in association with deeply scored covers similar in many respects to those of earlier periods. Distribution: Quirigua, San Agustín Acasaguastlan. There are in the Museum fragments of plain hollow prongs from Tajumulco (Dept. of San Marcos) and Asunción Mita (Dept. of Jutiapa). Two fragments of hollow plain prongs, presumably of Late Classic type from Zaculeu and Chalchitan (Dept. of Huehuetenango) were found among sherd lots (E-109, E-71 respectively), collected by A. L. Smith during his excavations at these sites in 1945 (Carnegie Institution, Yearbook 44:166–167). The specimen from Zaculeu is decorated with a vertical finger-indented fillet. They also occur at Travesía and the Sula Valley; Honduras. Fragments of deeply scored covers also occurred in Period III–IV deposits at Benque Viejo, British Honduras (Thompson 1940, Fig. 10a). Fragments of deeply scored covers are present in the Guatemala Museum collection from Capellania (Lot S-3) near the Rio Lempa and San

Miguel in El Salvador. Being surface finds, they are of unknown date.

Postclassic period. No type of three-pronged incense burner can yet be safely assigned to this period.

Even so tentative a classification as this shows that the three-pronged incense burner went through a long period of development and use without losing many of its basic characteristics. Fragments of one type or another have been found in deposits ranging from the earliest known Preclassic to the end of the Late Classic, except for a possible break in continuity during the Early Classic. This suggests that their production and use were motivated by a rather strong and fundamental religious ideology, probably in connection with a rain-god cult. Their spread throughout the Maya area is, to my mind, undoubted evidence of a spiritual impulse which brought about the dispersal of many related ideas. The region in which these ideas first took form and the routes along which they later traveled are unknown, but the quantity of material from the earliest periods at Kaminaljuyu suggests this site as its place of origin. The ceremonial significance of the three pronged incense burner is also open to speculation.

If these censers were indeed not made in Early Classic times, it is puzzling that their use did not die out during that period, although the associated cult might have, so to speak, lain dormant or perhaps been practiced in obscurity to blossom again in the Late Classic.

It is interesting that the apparent disappearance of these three-pronged incense burners during the Early Classic period and their reappearance with

moldmade features and slightly filtered form during the Late Classic in the Maya area seems to have been paralleled in the case of "rim-heads" vessels (see chart). Different types of rim-head vessels, similar in appearance and possibly in function, found outside the Maya area have been described under several names such as "inner handles of incensario covers" (Seler 1915c:495), "vessels with effigy handles" (Weiant 1943:112), "vessels with vertical modeled lugs" (Drucker 1943a:76), "vasijas con tres brazos huecos en el horde" (Armillas 1944), "bowls with inner handles" (Linné 1934:315). To avoid further confusion, it is proposed that the name "rim-head vessel" be applied to all such vessels. This evidence, although very vague, probably favors the theory advanced in my earlier publication (Note 97) that both complexes were motivated by the same, or at least a similar, religious concept. It is also interesting that the making of small clay figurines likewise appears to have ceased during the Early Classic and to have been resumed in Late Classic times, and that they too underwent the change from modeled to moldmade form.

The problems thus far stated and the questions posed are difficult to answer because of the relatively small amount of comparative material from other parts of the Maya area and adjacent regions. The three-pronged incense burner cult is merely one of many recently recognized Mesoamerican ceremonial complexes. As a new-born child, it has still to grow and should be handled with special care. New data from other areas may be expected to nourish this youngster who, given the proper archaeological food supply, should mature and demand well-merited attention.

Some Archaeological Specimens from Pomona, British Honduras

A. V. Kidder and Gordon F. Ekholm

During the winter of 1950 the writers and Mr. Gustav Strömsvik had opportunity to conduct an archaeological reconnaissance of the Bay Islands and north-west coast of Honduras and the southern coast and cays of British Honduras. This was made possible by Mr. Charles Sumner Bird, who, through the sponsorship of the Institute of Andean Research, chartered the yacht *Irmay* for the purpose. We are also under much obligation to His Excellency Ronald H. Garvey, Governor of British Honduras, for the necessary permit to explore and excavate in the Colony; as well as to Mr. W. H. Kieffer of the United Fruit Company, who assisted us in securing supplies and arranged for shipment of the large collection of potsherds obtained in Honduras and British Honduras.

The present note concerns a find made by Messrs. A. P. Bellhouse and H. D. Anderson of the Citrus Company of British Honduras Ltd, on the company's land at Pomona, in a fertile widening of the North Stann Creek Valley, some 18 km from the sea. There, in the course of clearing land for an orchard, it became necessary to remove one of the several mounds that prove the Pomona area to have been the site of a sizable ancient community. Permission to do this was obtained from the Governor by Mr. Frank Sharp, general manager of the company. In the operation two tombs came to light. Messrs. Bellhouse and Anderson removed their contents with great care and when we visited the place they asked us to take the specimens to Belize and deliver them to the proper authorities. This we did and after consultation with Governor Garvey, it was decided

that they should be temporarily deposited in the British Museum because of the danger of fire to the Belize Public Library building, which houses the colony's present archaeological museum. We were given permission to take the pottery vessels, which were badly crushed, to New York to be restored and studied.

The mound in question, now completely removed, was circular, about 27 m in diameter at ground level and with an estimated height of about 9 m. The mound fill contained a large amount of stone. Five plaster floors were encountered. The lowermost floor, pink in color, covered a platform about 60 cm thick and 16 m in diameter and composed of clay and river stone. The bottom of this platform was at approximately the level of the ground surface. The other plaster floors were unequally spaced vertically, the uppermost being fairly close to the highest point of the mound.

The most important feature of the mound was what we are calling Tomb I. This was a large rectangular chamber whose floor was the pink-colored plaster floor of the basal platform mentioned above. Only estimates of the tomb's size are available, but it would seem to have been something in the order of 5 m long, 1.2 m wide, and 2.1 m high. The tomb was in the eastern portion of the mound with the long axis running north and south. The excavators noted that one corner of the top of the tomb was about 30 cm below the slanting surface of the mound. The walls were built up of what the excavators thought were mortar bricks but which on examination of samples

102.1. Jadeite and shell: (a) section of longest of six similar jadeite tubular beads 9.3–10.3 cm long, all biconically perforated, ends cut square, Tomb II; (b) section of tubular gray stone bead (Fig. 102.5a) to show unusual method of perforation and square-cut ends, Tomb I; (c) section of jadeite earplug flare (Fig. 102.4i); note square cutting of edge of face and stem, Tomb I; (d) section of jadeite ornament (Fig. 102.4f); position of lower pair of triangular perforations indicated by dotted line; two pairs of triangular openings, each pair made by a single cylindrical drilling that pierced both sides of object, the triangular form produced by subsequent cutting at surface (see d'), Tomb II; (e) faintly incised lines on face of jadeite celt (Fig. 102.5c); apparently start of a decoration that was not completed, Tomb II; (f) sections (approximate) of perforated baroque pearls found in fragmentary condition, Tomb I; (g) design, drawn by Strömsvik from rubbing of badly eroded larger carved area on bivalve shell (Fig. 102.6a, b), Tomb I. All natural size.

shell, and an obsidian blade were on the floor along the west wall and another blade is said to have been lying beside the flat stone in the center of the tomb. The large earplug flare was standing on edge between the center and southern round stones just inside the entrance. A stack of bowls was also found near the southern end of the tomb.

A third feature of the mound was a pottery jar (containing only one bead) reported as being in the center of the mound on the bottom floor.

seemed to us to be a soft white limy material cut into squared blocks. Large slabs of granite, flat on one side, had formed the roof, but these had fallen down into the chamber. There was an entranceway toward the southern end of the east wall of the tomb.

Tomb II was a small rectangular chamber in the upper portion of the mound on the second floor from the top. It was placed well to the south of the center of the mound with its long dimension running east and west. This chamber would seem to have been something like 1.2–1.5 m long, 90 cm wide, and 90 cm high. Its roof was a single stone slab, and apparently the walls were constructed of the same kind of stone blocks described for Tomb I.

The objects found in the two tombs are listed below. Only a few notes can be given as to the arrangement of finds within Tomb I. On the floor were four round slabs of the same soft stone used in the walls. These were placed one in the center of the tomb, one in the center near the south end and two side-by-side near the north end. One of the small pottery bars was resting on one of the northernmost stones and contained a gray substance as well as a single bead. Two of the plates were found beside the southernmost stone. Two lots of beads, the carved

102.2. Jadeite earplug flare, Tomb I. We believe this to be the largest flare (i.e., forward-facing element of an earplug assemblage) found to date in Mesoamerica. Its great size (diameter averages 18 cm) renders it probable that it adorned a mask-headress or perhaps a wooden statue, rather than that it was worn in the ear. It is of highly polished dark green jadeite, with lighter mottlings. Edge of face and of stem cut squarely across. On either side of the stem is a conically drilled perforation 5–6 mm in diameter on exterior, 4 mm on interior. The central perforation was evidently drilled, as it is perfectly circular (diameter, 7.9 cm), the tool used having doubtless been a large hollow drill. On the back are five straight marks of a sawing tool, used vertically for the preliminary blocking out of the stem. The four glyphs on the face were incised with a sharp implement that produced smooth lines slightly less than 0.5 mm wide; in this and the enlarged photographs (Fig. 102.3) they have been filled with white powder.

- Earplugs, openwork, pair (Fig. 102.4g, h)
- Beads, tubular, ridged, 5 (Fig. 102.6d; 2 at lower left, 3 at right)
- Beads, tubular, ringed end, 5 (Fig. 102.6d, 1 shown at left)

- Beads, tubular, plain, 27 (Fig. 102.6d, strung)
- Beads, barrel-shaped, small, 1 (Fig. 102.6d, upper left)
- Univalve, carved exterior (Figs. 102.1g; 102.6a, b)
- Univalve, carved interior (Fig. 102.6c)
- Univalves, uncarved, fragments of at least 7 shells
- Pearls, baroque, 6 (2 shown in Fig. 102.1f)
- Sting-ray spines, 9
- Bone object, problematical (Fig. 102.4a)
- Pottery
- Basal-flanged bowl (Fig. 102.7a)

Basal-ridged bowl (Fig. 102.7b)

Straight-sided bowls, 3 (1 shown in Fig. 102.7c)

High-necked jar (Fig. 102.7d, also fragments of another)

Small plain ware dish (Fig. 102.7e)

Covered plain ware jar (Fig. 102.7f)

Plain ware jars, 2 (Fig. 102.7g, h)

Bulbous-legged bowl, fragmentary (Fig. 102.8a)

Bulbous-legged bowl, fragmentary (Fig. 102.8b)

TOMB II

Jadeite

Ornament, tubular, pierced (Figs. 102.1d; 102.4f)

Beads, tubular, 6 (Fig. 102.1a)

Celt (Fig. 102.5c)

Granite

Celt (Fig. 102.5d)

Descriptions of such of the foregoing objects as are illustrated are contained in the captions. Other specimens are:

TOMB I

Disc, crystalline hematite. Only fragments recovered. Cut to very true 2.5 cm circle; drilled 3 mm central perforation. Both faces highly polished.

Flake-blade, obsidian. Keenly pointed, lancet type similar to those of flint (cf. Fig. 102.5a). Fine

a

b

c

d

102.3. Glyphs on large earplug flare: enlarged photographs. J.E.S. Thompson states that these glyphs are undoubtedly early; their significance is unknown to him.

102.4. Jadeite, shell, bone: **(a)** fragment of problematic bone object, section in white, length 3.5 cm, Tomb I; **(b-e)** jadeite figurines from Tomb I, all highly polished; **(b)** light green finely mottled with white; T-shaped nose; back flat; transverse 3.5 mm perforation below ears; height 4.9 cm; **(c)** gray-green; eyes incised ovals, pupils indicated by small drillings; transverse oval (6 × 1 × 5 mm) perforation at neck level; from top of head a slightly conical drilling 6 mm at entry runs down 2 cm from which point a 2-5-mm cylindrical drilling extends to crotch; height 4.2 cm; **(d)** front white with emerald-green clouding, well-polished, back is less well-polished; features vaguely indicated; biconical perforation, diameter 5 mm at entries, passes through rounded back; height 3.8 cm; **(e)** clear apple-green; features vague eyes made by shallow conical drillings; transverse 3.5 mm cylindrical perforation at nose level; height 3.6 cm; **(f)** jadeite object (sectional drawing Fig. 102.1d); possibly element designed to protrude from flare of an earplug; light gray-green with fine white mottling; triangular cuttings a unique (?) feature in jadeite carving; height 3.2 cm, Tomb II; **(g, h)** shell earplugs with comma-shaped cutting in each of the five "petals" of the evened forward edges; beautifully fashioned pairs; in stem of g are two perforations 3 mm in diameter, 7 mm apart; **(h)** unperforated; diameter of face 3 cm, height 1.8 cm, Tomb I; **(i, j)** jadeite earplug flares, pair; very light green with emerald-green clouding; evidently cut from same piece of stone; admirable workmanship, high polish; grooves from points of scallops to throat perhaps made by string-sawing as they are slightly deeper at either end; flare i has single 3.5 mm cylindrical perforation in stem (section Fig. 102.1c); diameter, point-to-point, of faces, 4.4, 4.6 cm; height 1.5 cm; Tomb I.

102.5 (following page). Objects of stone: **(a) left**, stemmed spear-point or knife made from large core-struck flake of buff-colored flint; edges of stem and blade retouched; length 13.3 cm; surface, Pomona site; **right**, two very fine lancet-like flake-blades of gray flint with purplish streaks; very delicate retouch on upper part of edge of larger blade; lengths 12.415 cm; these are the only Mesoamerican flake-blades of flint of which we have record; Tomb I; **bottom**, tubular bead of gray stone, apparently not jadeite (for section showing unusual method of perforation, see Fig. 102.1b); length 7.2 cm; Tomb I; **(b)** slab of gray stone with face in relief; width of face 11.5 cm; Pomona site; **(c, c')** celt, blue-gray jadeite (?), glassy polish; on one face lightly incised lines, apparently an unfinished design (Fig. 102.1e); length 22.5 cm; Tomb II; **(d, d')** celt, igneous rock; length 16 cm; Tomb II.

e'

d'

102.6. Shell, jadeite: (a) univalve (*Spondylus pictorum*) with badly eroded carved areas, each showing two human figures kneeling face to face (drawing of larger area Fig. 102.1g); length 15 cm; Tomb I; (b) same, to show placement of carved areas; that at hinge end too eroded for reproduction; at either side of latter is a 1.6 cm cylindrically drilled hole; (c) fragment of shell of same species with carving on edge of interior, Tomb I; (d) ornaments of shell; upper left, small barrel-shaped bead, length 8 mm; below, three subspherical beads, diameter 1.2–1.4 cm; next below, one of five tubular beads with ringed end, lengths 1.7–2.5 cm; lower left and right hand row, tubular beads with encircling ridges, length 3–4.1 cm; middle string, plain tubular beads, lengths 2–3.3 cm; all shell beads cylindrically bored; all Tomb I; (e) ornaments of jadeite: upper left, tubular bead, gem-quality emerald-green, high polish, length 4 cm, biconical bore 4 mm diameter at ends; center left, pendant, inferior quality, grayish, length 3.2 cm, 3 mm transverse perforation at neck; lower left, inlay (9), gray, one side polished, other dull, length 1.3 cm; strung beads, first sixty-nine subspherical to discoidal, medium quality gray-green to apple green, well-polished, most specimens cylindrically, a few biconically, bored; diameter 7 mm–1.7 cm; terminal eight beads, small, irregularly shaped, gem-quality, high polish, bores cylindric, less than 1 mm; center, two beads with one ridged surface, fine light green, high polish, large cylindrical bore, diameters 1.6, 1.7 cm; all Tomb I.

retouching has rounded the butt and removed the flat remnant of the parent corers striking surface that is usually present on obsidian flake-blades. Length 9.7 cm.

Univalves, uncarved. All of same species as carved specimens.

Sting-ray spines. Very fragmentary. Apparently 9. Unworked.

Also from the Pomona site and illustrated and described in the captions are a fragmentary stemmed flint knife (Fig. 102.5,a) from the surface, and a carved stone slab, presumably from a building (Fig. 102.5b). Tomb I can confidently be assigned to the Early Clas-

102.7. Pottery (all vessels are shown in same relative size): **(a)** basal-flanged bowl; surfaces well-polished and covered with dark red slip on all except center bottom; has square-lipped ring base; paste is very soft and weak; diameter 32 cm, Tomb I; **(b)** basal-ridged bowl; surfaces well-polished with dark red slip covering all except inside of low ring base; a shallow groove occurs on the upper surface of the basal ridge; paste very soft and weak; diameter 36 cm, Tomb I; **(c)** straight-sided bowl, one of three nearly identical specimens; interiors are slipped light red and poorly polished; exteriors have sides polished, bottom rough; paste is soft and weak with a large amount of coarse temper; diameter 20 cm, all from Tomb I; **(d)** high-necked jar; a second similar specimen is fragmentary; a light-colored red slip covers all surfaces except inside of the low ring base; a shallow groove occurs at the juncture of neck and body, as well as one 2 cm above and one 1 cm below that point; paste is soft and weak; height 16 cm, Tomb I; **(e)** plain ware dish, unslipped and unpolished; diameter 11 cm, Tomb I; **(f)** barrel-shaped jar with cover; it is assumed that the cover belongs to the jar because of exact fit and the manner in which breakage occurred; surfaces are smoothed but unslipped; black firing clouds occur; bottom has four short solid legs; height 22 cm, Tomb I; **(g, h)** cylindrical jars; surfaces except bottoms are smoothed but unslipped, mottled brown to black; paste has abundant coarse temper; height 12 cm, Tomb I.

102.8. Pottery: **(a)** polychrome bowl; fragmentary specimen and with surfaces much eroded; decoration is red and black on light orange-red polished slip; presence of four supports clearly indicated; diameter 21 cm; Tomb I; **(b)** decorated bowl; fragmentary specimen; decoration is dark red on a reddish brown slip; further design might possibly have existed on exterior sides; four supports are indicated in the drawing, but this number cannot be certainly determined from the fragments preserved; height of side walls not certain; diameter 32 cm; Tomb I.

sic, the basal-flanged bowl being the "type fossil," so to speak, of lowland Maya sites of that period. Furthermore, the glyphs incised on the large jadeite earplug flare are, in J. E. S. Thompson's opinion, early. The age of Tomb II is problematical. It was above

Tomb I and may have been intrusive. It contained no pottery to date it. Sherds, in the ploughed land about the mound, were so few and so heavily weathered that we were unable to determine whether or not the site had been occupied beyond Early Classic times.

"Loop-Nose" Incense Burners in the Guatemala National Museum

Stephan F. de Borhegyi

In July 1950 the Guatemala National Museum received a donation from Don Guillermo Batres containing many interesting archaeological specimens which originally belonged to the private collection of his brother, the late Lic. Carlos Batres. It is thought that most of this material came from his property which formerly constituted part of the great archaeological site of Kaminaljuyu on the outskirts of Guatemala City. Numbered among the collection are three incense burners of particular interest. These were compared with three similar ones from the Dieseldorff Collection of the Guatemala National Museum., with four in the Chichicastenango Museum, and with four excavated by the Carnegie Institution of Washington at Kaminaljuyu. They appear to form a distinct type and I should like to designate them "loop-nose" incense burners.

The two almost identical incense burners from Kaminaljuyu used in this paper as type specimens, one of which is illustrated here as Figure 103.1a-c, were found when the top of an apparently Esperanza phase mound at Kaminaljuyu was leveled. For this and for other reasons to be discussed later, the incense burners dealt with in this paper have been assigned tentatively to the Early Classic period of the Maya area. However, before going into any further detail, a description of the five most characteristic specimens will be given.

FIGURE 103.1A-C (MUS. NO. 2709)

Collection: Excavated by the Carnegie Institution of Washington.

Provenience: Kaminaljuyu, near Mound A (Kidder, Jennings, and Shook 1946:211, Fig. 86).

Paste: Unslipped, coarse reddish brown ware tempered with minute mica particles.

Description: Two-chambered burner consisting of a tall bell-bottomed lower part with basal molding and a flaring sided receptacle. The division between top and bottom is marked on the exterior by a plain medial molding. A grotesque human face with ear- and noseplugs is modeled on the lower part and is flanked by two thin, rounded vertical flanges. The flange is edged with a row of applied clay buttons. Similar but pointed buttons have been applied to the exterior rim of the receptacle, giving it a scalloped appearance. A highly conventionalized, possibly human, face has been modeled on the receptacle above the lower face. It is characterized by two rectangular eyes on either side of a large projecting loop, giving the impression of a nose. Both eyes and nose are bordered with rows of clay buttons and the pupil of the eye marked by a larger applied clay disc. A small x, modeled animal head is applied to the middle of the "loop-nose," the eyes of which are represented by applied clay pellets. The receptacle is also flanked by thin, rectangular, vertical side flanges giving the impression of being the ears of the conventionalized human face. These are decorated with clay rolls. The vessel is partly restored. Traces of red and blue-black paint and traces of a thin white wash are still visible. The interior of the receptacle is smoked.

Dimensions: Ht. 23 cm, diam. 27.5 cm.

103.1. Loop-nose incense burners.

Comparative material: A two-chambered coarse ware incense burner said to be from San Andres Sajcabaja (Dept. of Quiche, Guatemala) similar to this specimen but lacking the "loop-nose" is illustrated by Lothrop (1936, Fig. 85). This incense burner is now in the Chichicastenango Museum (Mus. N o. 477) where it forms part of the Rossbach Collection.

FIGURE 103.1D, E (MUS. NO. 2337A)

Collection: Batres.

Provenience: Unknown, probably Kaminaljuyu.

Paste: Unslipped, coarse reddish brown ware containing mica and quartz particles.

Description: Two-chambered burner with bell-bottomed lower part and flaring-sided receptacle. On the lower part is modeled a grotesque human face with applied clay buttons representing nose-plugs. The circular eyes were made by a deep, even incision, possibly by a bone impression. On each side of this face is a rounded flange bearing in its center an applied bone impressed clay disc representing an earplug. Above each flange is a small modeled

animal-head similar in many respects to the animal head of Figure 103.1a, b.

The vertical side flanges on the wail of the receptacle are now missing but long scars directly above the lower flanges indicate their former presence and position. Although the eyes of a conventionalized face, such as observed on Figure 103.1a, b are present, a "loop-nose" decorated with applied clay buttons protrudes from the wall of the receptacle. The union of receptacle and lower part is marked on the exterior by a medial molding bordered with projecting clay buttons. The rim of the receptacle was bordered with rectangular projections, most of which are now broken off, together with a portion of the rim itself.

Traces of red paint and white wash are present and the interior of the receptacle is smoked.

Dimensions: Ht. 21 cm, diam. 25 cm.

FIGURE 103.1F, G (MUS. NO. 2337B)

Collection: Batres.

Provenience: Unknown, probably Kaminaljuyu.

Paste: Unslipped, coarse, reddish brown ware containing mica and quartz particles. .

Description: Two-chambered incense burner with bell-bottomed lower part and flaring-sided receptacle. The lower part is undecorated.

A grotesque, modeled, flat human face with coffee-bean eyes and nose- and earplugs is applied to the wall of the receptacle. On either side of the grotesque face are applied small animal heads, similar to those already described for Figure 103.1a–e. The one remaining vertical side flange is decorated with a clay roll in the form of a scroll. The rim of the receptacle as well as the medial molding is decorated with applied rectangular protuberances.

The conventionalized face, characterized by rectangular eyes and "loop-nose," such as in Figure 103.1a–c, is missing but instead the modeled, realistic though grotesque, human face is applied in such a way, partly to the wall of the receptacle and partly to the medial molding, that an opening reminiscent of the loop is left between face and wall. A large portion of the receptacle is missing.

Traces of white wash are visible on the exterior of the entire vessel. The interior of the receptacle is smoked.

Dimensions: Ht. 19.5 cm, diam. approx. 25 cm.

Comparative material: A somewhat similar two-chambered incense burner is in the Chichicastenango Museum (Mus. No. 698). Unfortunately it is of unknown provenience.

FIGURE 103.2A, B (MUS. NO. 5841)

Collection: Dieseldorff.

Provenience: Unknown, possibly Alta Verapaz.

Paste: Unslipped, coarse brown ware containing mica and quartz particles.

Description: Two-chambered incense burner consisting of a bell-shaped lower part and a flaring-sided receptacle.

On the lower part is modeled a grotesque human face with coffee-bean eyes and a large noseplug. Originally an earplug had been on either side of the face but one has since been broken off. Behind each ear is a small thin vertical side flange. The division between receptacle and lower part is marked by a plain medial molding.

Although no eyes of a conventionalized face are present, a "loop-nose" protrudes from the wall of the receptacle and is decorated with rows of applied circular clay buttons. The receptacle is flanked by two rounded vertical side flanges decorated with clay rolls in a manner similar to Figure 103.1a–c. On either side of the loop were originally four small modeled animal heads, two now partly and one entirely broken off. The rim of the receptacle is decorated with applied rectangular clay protuberances.

No traces of a paint or wash are visible. The interior of the receptacle is smoked.

Dimensions: Ht. 23 cm, diam. 27.3 cm.

FIGURE 103.2C, D (MUS. NO. 5324)

Collection: Dieseldorff.

Provenience: Unknown, possibly Alta Verapaz.

Paste: Unslipped, coarse brown ware containing mica and quartz particles.

Description: Two-chambered incense burner consisting of a tall cylindrical lower part with basal molding and a flaring sided receptacle.

On the receptacle is a highly conventionalized, possibly human, face, with rectangular eyes bordered with rows of clay buttons. The pupil is marked by a larger applied clay disc. A large "loop-nose" with similar decoration protrudes from the plain medial molding, thus forming a bridge between the receptacle and the otherwise undecorated cylindrical lower part. This face is flanked by two rectangular vertical side flanges. Below each flange is an applied clay disc resembling an earplug and suggesting that the; flanges may represent ears, as already seen to be the case in Figure 103.1a–c. The rim of the receptacle is decorated with applied pointed buttons, many of which are now broken off.

c

d

e

103.2. Loop-nose incense burners.

Faint traces of red paint are still visible on the exterior of the vessel. The interior of the receptacle is smoked.

Dimensions: Ht. 24 cm, diam. 28.5 cm.

Comparative material: Another incense burner, similar in many respects to the one just described but more elaborately decorated, is illustrated by Lothrop (1936, Fig. 84) and reproduced here as Figure 103.2e. It is said to be from San Andres Sajcabaja (Dept. Quiche, Guatemala). This specimen is now in the Chichicastenango Museum (Mus. No. 588) where it

forms a part of the Rossbach Collection. (cf. also a two chambered incense burner in the same collection, Mus. No. 298, which has a circular decoration on the lower cylindrical part of the vessel similar to that seen on Lothrop's Fig. 84. It is of unknown provenience.)

Although from different geographical locations (Kaminaljuyu, San Andres Sajcabaja, and possibly Alta Verapaz), it is obvious that the specimens described here have a great many features in common. These may be listed as follows:

1. Two-chambers consisting of a tall bell-bottomed or cylindrical lower part and a flaring-sided upper receptacle, the latter used for the burning of incense as indicated by the smoked interior: all specimens.

2. Presence of a medial molding, 'plain or decorated, marking on the exterior the division between receptacle and lower part: a. Plain molding: Fig. 103.2; Lothrop 1936, Fig. 85; b. Decorated molding: Fig. 103.1; Lothrop 1936, Fig. 81.

3. Presence of a grotesque modeled human face on the bell-bottomed lower part (one exception is Fig. 103.1f, g in which it appears on the receptacle): Figs. 103.1a–e; 103.2a, b; Lothrop 1936, Fig. 85.

4. Presence of a highly conventionalized, possibly human, face on the flaring-sided receptacle, consisting of rectangular eyes, projecting "loop-nose" and flange-ears. All features are bordered with rows of applied clay buttons or rolls. a. Projecting "loop-nose" with eyes, Figs. 103.1a–c; 103.2c–e; Lothrop 1936, Fig. 85. b. Projecting "loop-nose" without eyes, Figs. 103.1d, e; 103.2a, b.

5. Presence of small, applied animal heads, the eyes of which are represented by small clay pellets. Lothrop (1936:84) suggests that they may represent birds' heads: Figs. 103.1; 103.2a, b; Lothrop 1936, Fig. 85.

6. Presence of applied, pointed, rounded or rectangular protuberances from the rim of the flaring-sided receptacle, giving the rim a scalloped-edge appearance: all specimens.

7. Presence of vertical, rounded or rectangular, side flanges decorated with clay rolls or rows of clay buttons: all specimens.

As can be seen, the most outstanding feature characteristic of this group is the "loop-nose." In certain cases it definitely forms part of a conventionalized, probably human, face although on other incense burners its original meaning seems to have been lost and it appears alone.

In Figures 1d, e and 2a, b the "loop-nose" is placed directly above the grotesque human face in such a way that it gives the appearance of a headdress. This is especially noticeable in Figure 103.1d, e. On this line of reasoning, figures 103.3 and 103.4 appear here to show a probable later or parallel development. The loop on these specimens appears as a definite headdress and the abundant use of clay

buttons brings about a further resemblance to the former group in spite of the fact that they are not necessarily two-chambered.

FIGURE 103.3A–D (ANTHROPOMORPHIC INCENSE BURNER FOUND AT KAMINALJUYU, MOUND A, TOMB VI, MUS. NO. 2485 [KIDDER, JENNINGS, AND SHOOK 1946, FIGS. 87, 201I, 207G]).

This elaborate and fragile specimen consists of a two-chambered incense burner and a tall anthropomorphic cover. When found, the receptacle was filled with ashes and charcoal. The cover of the incense burner represents a seated figure wearing a tall loop-headdress. The specimen comes from an Esperanza phase tomb. (For color and detailed description see Kidder, Jennings., and Shook 1946:210–12 and Fig. 207g) Total ht. 37 cm, diam. of receptacle 15.5 cm.

A similar incense burner represents a seated figure holding a shallow scalloped-edge pan over its crossed knees (Lothrop 1936, Fig. 101). It is said to have been found near Rabinal, Dept. Baja Verapaz, and is now in a private collection in Germany.

FIGURE 103.3E, F (MUS. NO. 5821; DIESELDORFF COLLECTION)

This coarse, brown ware incense burner is believed to have come from the region north of Coban in Alta Verapaz (Villacorta 1938:261). The features of the modeled effigy face of this tripod incense burner bear, in spite of its realistically represented teeth, a strong resemblance to those of Figures 103.1 and 103.2a, b. The "loop-nose" is here used as a headdress. The rounded, vertical side flanges bordered by clay scrolls; and the rows of rounded or pointed clay buttons outlining the "loop" and the rim, show a further connection with the two chambered group discussed earlier. The major difference is that the flaring-sided receptacle rests on three hollow cylindrical feet instead of on a bell-bottomed lower part.

The specimen bears traces of red paint and white wash. The interior of the receptacle is smoked. Ht. 25 cm, diam. 23.5 cm.

FIGURE 103.4A, B (MUS. NO. 2351; BATRES COLLECTION)

This tripod incense burner is said to be from Kaminaljuyu. It is made from a coarse, reddish brown ware heavily tempered with quartz particles.

The vertical side flanges are edged with rows of applied, perforated clay buttons. The finely modeled, grotesque human face has an open mouth and the

a

b

c

d

e

f

a

b

c

d

e

f

upper canines are sharply pointed. The "loop-nose" appears in the form of a protruding headdress encircled by a realistically modeled snake. Two similar snake heads with applied pellet eyes protrude from the earplugs on either side of the face. The fact that these animal heads represent snakes suggests that the small animal heads already described on the two-chambered incense burners may also represent conventionalized snake heads rather than birds as proposed by Lothrop (1936:84). The hollow, cylindrical feet of the incense burner are open at the bottom.

Traces of red and blue paint and white wash are visible. The interior of the receptacle is smoked. Ht. 21 cm, diam. 19.5 cm.

FIGURE 103.4C, D (MUS. NO. 7560; DONATION OF MRS. NORMAN PUTNAM REAM OF GREENWICH, CONNECTICUT; PURCHASED IN PATZUN, DEPT. CHIMALTENANGO, GUATEMALA, BUT OF UNKNOWN PROVENIENCE).

This two-chambered incense burner is of a coarse brown ware containing mica and quartz particles. The vessel consists of a slightly flaring-sided receptacle with wide everted rim and a tall cylindrical bottom part which is perforated at the back side. The vertical side flanges as well as part of the rim are now broken off.

The skillfully modeled human face with open mouth, nose and earplugs, is applied to the bottom part. The earplugs and a beard-like protuberance are decorated with applied clay discs and the collar is bordered with a clay roll. The "loop" appears as a headdress similar to that on Figure 103.4a, b but it is compressed. The face with its heavy eyebrows, the details of the headdress and the collar are similar in many respects to the corresponding features on Figure 103.4a, b.

Traces of red paint are present. The interior of the receptacle is smoked. Ht. 26 cm, diam. 19 cm at inner rim.

Another vertical side-flanged, two-chambered effigy incense burner with compressed "look-nose" headdress is illustrated by Seler (1901, Fig. 257). It is in the Adams Collection in the Vienna Museum and is said to have come from Alta Verapaz. It is reproduced by Walter Lehmann (1921:8, Fig. 46).

FIGURE 103.4E, F (MUS. NO. 2708; KIDDER, JENNINGS, AND SHOOK 1946, FIG. 202A).

This tripod effigy incense burner with vertical side flanges was found during the digging of a drain north of Mound B at Kaminaljuyu and is believed

to belong to the Esperanza phase. It is of a coarse, reddish brown ware containing quartz particles. The grotesque face with large applied ear- and nose-plugs is modeled on the vessel wall. Although not bearing a "loop-nose" headdress, it is of interest because of the curious flat clay loop that extends from the upper lip of the grotesque human face to the collar. This collar or necklace bordered with a row of applied clay buttons is similar to those seen on Figure 103.3. It is very possible that this flat loop, whatever its purpose, bears a direct connection with the "loop-nose." It is also interesting to note that this skillfully modeled effigy head has an open mouth and what appear to be pointed teeth but from the front, at least, the mouth is completely hidden by the wide loop. This specimen also has hollow cylindrical feet which are open at the bottom.

The vessel bears signs of red and yellow paint and white wash. Ht. 51 cm, diam. 30 cm. It is always hard to say which comes first, the chicken or the egg. That we have a certain type of stylistic evolution is obvious. Whether the "loop-nose" originated as such and evolved into the headdress and finally dropped to its curious location between the nose and the collar or vice versa is the question. The fact that all pieces are presumably Early Classic even presents the possibility of parallel development although this is less likely.

To students interested in style evolution or for the amusement of archaeologists disdainful of such theorizing, I would like to suggest the following stylistic sequence: Figures 103.2c-e; 103.1a-c; 103.2a, b; 103.1d, e; 103.3.e, f; 103.4a, b; 103.4c, d; and 103.4e, f. It is, however, far from my desire to copyright this!

Before closing, I wish to call attention to two hollow, cylindrical pottery objects from Uaxactun (Dept. Peten, Guatemala), each representing a conventionalized grotesque human face (Ricketson and Ricketson 1937, Fig. 191, Pl. 95e-g). They are now in the Guatemala National Museum (Mus. Nos. 293, 295). The nose of each face is a loop-like projection. The vertical side-flanges as well as the rim are decorated with rows of applied clay buttons. Although their interiors show no signs of smoking, Ricketson and Ricketson (1937:282, Fig. 191b) suggests their use as incense burners and compares their features with some of the grotesque masks on Pyramid E-VII-sub. These "loop-nosed" pottery cylinders were found in Cache 13 in the upper part of Pyramid E-VII and are believed to be from the Tzakol phase of the Early Classic period of the lowland Maya.

It has long been realized that a more detailed knowledge of Maya incense burners is greatly needed. Until sufficient examples of these important cult vessels can be studied and classified any attempt at a

typology can be only tentative. The material presented here is but a small contribution to a field which is enormous in its scope and implications. Nevertheless, the recurrence of those features already discussed suggests that they can be used as guides for assigning incense burners of similar stylistic treatment to the Early Classic period of the Maya area.

It is interesting to note that three two-chambered incense burners with many characteristics similar to

those noted in this paper were encountered during the United Fruit Company's excavations at Zaculeu (Dept. Huehuetenango). These vessels were found in tombs under Structure 1 and are believed to date from the Early Classic period. More detailed information concerning these specimens will be forthcoming in the Zaculeu report by Trik and Woodbury.

This study was made possible by a grant-in-aid from the Bollingen Foundation of New York.

GUATEMALA CITY

Ethnological Material from British Honduras

William R. Coe and Michael D. Coe

While excavating not far from the village of Socotz, in the Cayo District of British Honduras, during the summer of 1949, our Maya workmen supplied us with some interesting ethnological material. The story was told to us by Ascension Alfaro, an Indian born in the vicinity of Lake Peten Itza in Guatemala, where he learned the tale. The rest of the material was given us by Jacinto Cunil, our foreman from Socotz.

THE STORY OF THE SNAIL (U TZICBAL IX MAN URICH)

Once upon a time a farmer had a corn shed in his milpa. A bold squirrel came to eat the farmer's corn. In the milpa shed lived Aunt Snail (*Ix Man Urich*) on one of the rafters. When Aunt Squirrel (*Ix Man Cuuc*) suddenly arrived to eat corn, the little snail warned her that the owner of the milpa was coming by singing, "Here comes the owner of the milpa, he has his *jicara*, he has his calabash, he has his *posole*, *thararu*!" But she paid no attention. While this was going on, the owner of the granary came and saw Aunt Squirrel and fired his gun and killed her. The man did this, then he got up a load of corn and returned to his house. He forgot all about Aunt Squirrel.

When night came Aunt Snail began to sing, "Here comes the owner of the milpa, *mamavenita*, he has his *jicara*, he has his calabash, he has his *posole*, *thararu*!" During this Aunt Mole (*Ix Man Bah*) came and began to dance, "*Bahcitinbahcin*, *bahcitinbahcin*!" During this dance the spotted agouti (*tzub*) arrived. It began

to sing, "*Thinthinwegweg*, *thinthinwegweg*!" The deer (*ceh*) came. It started to whistle, "*Pucunpucun pux*, *pucunpucun pux*!" The peccary (*citam*) arrived. It began to sing, "*Cilim thapthah*, *cilim thapthah*!" The armadillo (*weeh*) came. It began, "*Zip zip zip*!" The curassow came, it was already dawning. It began, "*Martha haha*, *tzaten in wenel anha*, *martha haha*, *tzaten in weasel anha*!" The cox (the quail or cojolito; *Penelope purpurascens* Wagl., a black pheasant-like bird) came. It saw while flying that the owner was coming with his shotgun and warned them, screaming, "*Wai wai wai* (here, here, here)!" and it set off in flight.

It was already daylight. The owner came and heard the uproar of the animals which ran and flew. They were watching over Aunt Squirrel who was on the roasting spit.

Among the Maya of Socotz, there is a firm belief in the existence of a monster known as the *zizimit*. This is a huge, hairy, ape-like creature of great strength. It has no knee joints and its feet are turned backwards. There are both male and female *zizimites*. The *zizimit* carries off sinners by persuasion or force to a cave, where it eats the person of its own gender, but only the lower half of the body. There are two ways to avoid capture: (1) When known to be followed, one runs into the bush and hides; the monster will trail one to the spot, but missing the sight and sound of its quarry, it will then notice its own footprints pointing in the opposite direction to those of its intended victim; the *zizimit* turns and hurries back along the trail. (2) When one notices

the *zizimit* close behind, one starts dancing, laughing, and whirling around and around; the monster, liking to dance, will at once copy one's steps, whirling around and laughing until it becomes dizzy and falls; then one escapes.

It is apparent that this monster is the same as the *mahanamatz* or *sisimito* of the Kekchi Maya to the south (see Thompson 1930:67). Among the Kekchi, one avoids it by setting its shaggy coat on fire. It is also quite clear that the *zizimit* is the *Tzitzimitl* of the Aztec. Of the *Tzitzimime* (plural of *Tzitzimitl*) Sahagun says, "... there was a great eclipse of the sun. It was very dark for five hours for the stars appeared and the people were very afraid, and they said that some monsters, which they called *Tzitzimis* had to descend from the sky and eat men and women" (Sahagun 1938, Bk. 8, Ch. 1). Thompson (1950:85) says, "In Mexican belief the *Tzitzimime* were certain stellar deities who had at one time been posted at the four corners of the earth, and supported with upraised arms the heavens. They were believed to fall head first to earth at certain times, notably during the darkness of eclipses, and in the course of these descents to eat men and women." Thompson identifies the Mexican *Tzitzimime* with the Maya Bacabs. The more frightening aspects of the mon-

ster have been passed down into folk belief, but for some strange reason the Maya of British Honduras retain the Mexican rather than the Maya name. The pottery figurines occasionally found in the mounds are regarded as the owners of the mounds and are called by the Indians *ku kat* (clay gods). It is thought that they were made by an ancient race of little men called the *p'uz*. The figurines are extremely dangerous, and if one happens to dig one up and it falls to any other direction but south, then sickness and even death may result (this is somewhat peculiar since south was probably the region of the death god). As a matter of fact, this did happen a few years ago to an Indian named Bruno Dzib. He chanced to turn up in his milpa a little Formative head of clay (these are the most powerful, as evil winds can come from the punched eyes and mouth). The winds entered his body, since the head did not fall to the south, and he died in a few days. We have the head, and the story was told us by several people, all of whom agreed on the cause of Dzib's death. The Indians also speak of the *yumikat*, who are said to be *alux* (little goblins) living in pottery vases in the ruins. No right-minded excavator would dare to dig into a mound without first propitiating the spirits inside with copal incense and prayers.

CAMBRIDGE, MASS.

Further Notes on Three-Pronged Incense Burners and Rim-Head Vessels in Guatemala

Stephan F. de Borhegyi

During March 1951, I spent a weekend at Finca El Progreso near Chiquimulilla, Department Santa Rosa, at the invitation of the owner, Faustino Padilla. The purpose of my visit was to investigate the spot where a three-pronged incense burner now located in the Guatemala National Museum (Fig. 97.7) was found in 1936. It was discovered, together with another fragmentary specimen, by the members of the Padilla family during the digging of a drainage canal connecting a natural spring with a wash basin. I had hoped that more material could be obtained by further excavation at the same spot and by a survey of the area. This unfortunately was not the case. The soil around the drainage canal where the incense burner was found proved to be sterile. The nearest archaeological site with mounds and surface material was located on the finca property at the west end of the sulphur lake, Ixpaco, approximately 2 km south of the drainage canal. The surface material from this site, called Terreno Dauro, ranged from Preclassic to Late Classic. It therefore seems possible that the inhabitants of this site may have presented the three-pronged incense burners as offerings to the spring, a custom not infrequent among the ancient Maya (Smith and Kidder 1943:144).

More successful was the examination of the private collection of the Padilla family which revealed fragments from two more three-pronged incense burners, one of which (Fig. 105.1, 2) was mentioned in the preceding paragraph. Lic. Padilla kindly presented both of them to the Guatemala National

Museum, where they were later partially restored (Fig. 105.1a, b).

FIGURE 105.1A. CYLINDRICAL THREE-PRONGED INCENSE BURNER, FRAGMENTARY.

Paste: coarse, unslipped and unpolished yellowish-gray ware, thickly sown with quartz and mica particles.

Description: the three prongs are now missing but are indicated by scars on the flat top. The prongs were not encountered during the unearthing of the specimen or later in my supplementary investigation. In the center of the top is a circular indentation, the purpose of which is unknown (cf. Note 101). It may have been used as a container for copal incense. The specimen was very fragmentary and its reconstruction is only tentative. The notches in the cylindrical wall of the censer suggest that it was decorated with a delicate openwork design consisting of three horizontal rows of U-shaped perforations. The fragmentary condition of the specimen can probably be attributed to this decorative technique. Traces of thin, yellowish-white, calcareous wash are present on the exterior. Only the flat top of the incense burner is smoked. It should be noted that in spite of the fact that the specimens were said to have been found near the spring, none of them was water worn.

Dimensions: approximate ht. (without prongs) 26 cm, approximate top diam. 21 cm.

Provenience: Finca El Progreso (Dept. Santa Rosa). Museum Lot E-199.

105.1. Three-pronged incense burners and rim-head vessels.

Chronological position: Early Preclassic.

Associated material: the specimen was found with the three-pronged incense burner illustrated in Fig. 97.7. The two incense burners are very similar, the principal difference being that the openwork design of the latter is made up of triangular rather than U-shaped perforations.

FIGURE 105.1B. CONE-SHAPED EFFIGY PRONG FROM THREE-PRONGED INCENSE BURNER.

Paste: coarse, unslipped and unpolished, yellowish-red ware thickly sown with white volcanic tuff and mica particles.

Description: the head is that of a bearded individual with shallow incisions suggesting tear streaks under the coffee-bean eyes (Kaminaljuyu rain god?). The ears or ear plugs are perforated. Under the chin of the effigy is an opening (diameter 2.5 cm)

made while the clay was wet. Three tool-indented fillets stretch from the top to the base of the prong on the back of the head. The specimen shows slight smudging.

Dimensions: ht. of prong 10.5 cm.

Provenience: Finca El Progreso (Dept. Santa Rosa). Museum Lot E-99A. Surface find from the archaeological site, Terreno Dauro.

Chronological position: Early Preclassic

Comparative material: similar cone-shaped, modeled effigy prongs with tear streaks have been reported from Kaminaljuyu, Guatemala (Fig. 97.5b, e, f).

Later in March I visited the highlands of Guatemala with the purpose of tracking down more examples of three-pronged incense burners. In Quezaltenango in the private collection of Don Vitalino Robles I located three specimens, said to have come from the east bank of the Rio Samala near the town of Salcaja (Dept. Quezaltenango). Sr. Robles

kindly gave permission to publish these specimens (Figs. 105.1c, d, e; 105.2).

FIGURE 105.1C; 105.2A, B. THREE-PRONGED, CYLINDRICAL INCENSE BURNER WITH HOLLOW, PLAIN PRONGS.

Paste: unslipped, unpolished reddish-brown ware with a slightly darker paste thickly sown with particles of quartz and mica temper.

Description: two of the prongs are broken off near the top and the third is entirely missing, its former presence indicated by a scar. A ridge, 10.5 cm long, was applied to the center of the convex top of the incense burner. It lies between but does not connect the frontal prongs as noted on the Late Preclassic incense burners described in Note 101. Around the base of the specimen is a row of horizontally applied clay protuberances generally referred to as "spikes." On either side of the censer is a circular vent 2 cm in diameter.

Dimensions: ht. (without prongs) 8 cm, top diam. 23 cm.

Provenience: east bank of the Rio Samala near Salcaja (Dept. Quezaltenango), Robles Collection.

Chronological position: probably Late Classic.

Comparative material: hitherto unknown type. This is the only Late Classic three-pronged incense burner noted with "spiked" decoration although flaring-sided, flat-bottomed spiked incense burners are common during this period in the Guatemala highlands (Kidder, Jennings, Shook 1946:239), (For Early Preclassic spiked three-pronged incense burners see Note 97).

FIGURE 105.1D, E; 105.2C, D. TWO EFFIGY PRONGS WITH MOLDMADE HUMAN FACES.

A. HOLLOW, EFFIGY PRONG WITH APPLIED HUMAN FACE ON THE SUPERIOR HALF.

Paste: coarse, unslipped, yellowish-brown ware containing particles of quartz and mica.

Description: the features of the face were mold-made but the sharply filed teeth were made by crude incisions. The earrings are represented by applied, flat clay buttons. Three similar but smaller buttons decorate the forehead. A narrow slit is under the chin (cf. Note 101). A circular vent, 1.5 cm in diameter, is on the back near the base. The exterior of the prong is slightly smudged.

Dimensions: ht. 24 cm, basal diam. 7 cm.

Provenience: same as Figures 105.1c; 105.2a, b.

Chronological position: probably Late Classic.

Comparative material: Fig. 101.5a, b.

B. HOLLOW, EFFIGY PRONG WITH APPLIED HUMAN FACE ON INFERIOR HALF.

Paste: coarse, unslipped, reddish-brown ware thickly sown with mica and quartz particles.

Description: the face appears to be that of an old man although part is missing. The sharply filed teeth were made by crude incisions. The peaked headdress is made of a clay roll which borders the face and is decorated with applied clay knobs. The right earplug (left one missing) is represented by a clay button with central thumb impression. A narrow slit is present under the chin. A circular vent, diameter 1.3 cm, is at the back of the prong, close to the top. The tip of the prong shows same signs of abrasion and the exterior surface is slightly smudged.

Dimensions: ht. of prong 23.5 cm, basal diam. of prong 9 cm.

Provenience: same as Figures 105.1c; 105.2a, b.

Chronological position: probably Late Classic.

Comparative material: same as Figures 105.1d; 105.2c.

DISTRIBUTION OF THREE-PRONGED INCENSE BURNERS AND RIM-HEAD VESSELS IN GUATEMALA

In Note 101 an attempt was made to show by means of a chart the distribution and occurrence of three pronged incense burners and rim-head vessels. Although no changes need be made in the material presented at this time, it is far from complete. Now that a thorough survey has been made of the material located in the sherd laboratory of the Guatemala National Museum, an up-to-date list has been compiled of the distribution of this complex according to departments and individual archaeological sites in Guatemala. This is supplemented by a distribution chart (Table 105.1).

Any specimen not excavated under strict archaeological conditions has been placed in a chronological horizon on the basis of typology. All such material is therefore specified in the following list as being of a particular chronological type (such as Late Classic type). Those specimens assignable to a particular period on the basis of stratigraphy or association are placed within the chronological horizon without the use of the word type.

The features characteristic of each period and on the basis of which typological classification has been made were listed and discussed in detail in Note 101, as well as in a chart (Table 101.1). The reader will therefore be referred to this Note for any further information.

*a**b**c**d*

105.2. Three-pronged incense burners and rim-head vessels.

The letters CH, S, and M stand for the Las Charcas, Sacatepequez and Miraflores phases, respectively. The number in parentheses represents the number of fragments of three-pronged incense burners, their deeply scored covers, or rim head vessels. The 22 departments of Guatemala are listed alphabetically.

ALTA VERAPAZ

Chipoc (near Coban), Lot No. C-48, from excavation by R. E. Smith. Three-pronged incense burners: (16) Late Classic; deeply scored incense burner covers: (8) Late Classic.

Santa Elena (near Coban), Lot No. A-29, from surface collection by R. E. Smith. Deeply scored incense burner cover: (1) Late Classic type (?).

BAJA VERAPAZ

Tzalcam (near San Jeronimo), MN 4304, specimen purchased by O. G. Ricketson. Rim-head vessel (?): (1) Late Classic type (?).

CHIMALTENANGO

La Alameda (near the city of Chimaltenango), Lot No. R-21, from ancient pits and graves near school building, excavation by E. M. Shook. Three-pronged incense burner: (1) Early Preclassic (S).

Roosevelt Highway (near the city of Chimaltenango), Lot Nos. R-6, R-6a, from ancient pits and graves on north edge of road, excavation by E. M. Shook. Three-pronged incense burners: (4) Early Preclassic (S); deeply scored incense burner covers: (6) Early Preclassic (S).

CHIQUMULA

No evidence of complex.

ESCUINTLA

El Baul, Lot No. J-21, from various levels of Trench 9 (see Thompson 1948, Figs. 25, 35; and Note 101). Rim-head vessels: (7) Late Classic (San Juan phase).

Tiquisate (1) Ticanlu Farm, Lot Nos. J-11, J-12, from surface collection by E. M. Shook. Rim-head vessels: (7) Late Classic type.

Toliman Farm, Lot No. J-25, from Larrave private collection. Rim-head vessel: (1) Late Classic type. (3)

Tacana Farm, Lot No. J-13a, from surface collection by E. M. Shook. Rim-head vessel: (1) Late Classic type.

Section Z-5, Lot No. J-16, from cut of drainage canal, excavation by E. M. Shook. Rim-head vessel: (1) Late Classic.

Zunil Farm, Lot No. J-9b, from second level, test excavation by E. M. Shook. Rim-head vessels: (4) Late Classic.

Solola Farm, Lot No. E-30, from surface collection by E. M. Shook. Rim-head vessels: (4) Late Classic type.

Texcuaco (near Rio Coyolote), see Note 101. (Pullin collection). Rim-head vessels: (5) Late Classic type.

GUATEMALA

Kaminaljuyu area (near Guatemala City), various C Lot numbers, the bulk of the material from ancient pits and mounds excavated by A. V. Kidder and E. M. Shook (see also Fig. 97.16 in and Figs. 101.1, 101.2, 101.3a, 101.5c). Three-pronged incense burners: (92) Early Preclassic (CH, S); three-pronged incense burners: (204) Late Preclassic (M); three-pronged incense burner covers: (166) Early Preclassic (CH, S); deeply scored incense burner covers: (157) Late Preclassic (M); rim-head vessels: (246) Late Preclassic (M).

Amatitlan (Contreras Yacht Club site), Lot Nos. E-5, E-8, from surface and fill of mounds, excavation by A. V. Kidder and E. M. Shook. Deeply scored incense burner covers: (3) Late Preclassic (M).

Canchon (near Guatemala City), Lot No. E-33, from surface collection from mound group by E. M. Shook. Three-pronged incense burners: (1) Late Preclassic type (M); deeply scored incense burner covers: (2) Late Preclassic type (M).

Finca Barcena (near Guatemala City), Lot No. E-54, from surface collection by E. M. Shook. Deeply scored incense burner cover: (1) Late Preclassic type (M).

El Portillo (Guatemala City), Lot No. E-50, surface collection by E. M. Shook. Three-pronged incense burner: (1) Late Preclassic type (M); deeply scored incense burner covers: (2) Late Preclassic type (M).

Jorgia (near Canchon), Lot No. E-28, from surface collection by E. M. Shook. Deeply scored incense burner cover: (1) Late Preclassic type (M).

Los Arcos (Guatemala City), Lot No. E-48, from surface collection by E. M. Shook. Three-pronged incense burner: (1) Early Preclassic type (CH).

Piedra Parada (near Canchon), Lot No. E-9, from road cut near mound group, collection by E. M. Shook. Deeply scored incense burner covers: (5) Late Preclassic (M).

HUEHUETENANGO

Chalchitan, Lot No. E-71, from below ball-court floor between Structures 23 and 24, excavation by A. L. Smith. Three pronged incense burner: (1) Late Classic.

Cambote, Lot No. E-88, from surface collections by A. L. Smith and E. M. Shook. Three-pronged incense burners: (4) Late Classic type; deeply scored incense burner cover: (1) Late Classic type.

Zaculeu, Lot No. E-109, from Pit X, excavation by A. L. Smith. Three-pronged incense burners: (5) Late Classic.

105.3. Map showing distribution of three-pronged incense burners and rim-head vessels.

IZABAL

Quirigua, Lot Nos. E-117, E-117b, from principal plaza and from Pit 7 in the cobble pavement, excavation by G. Stromsvik. Three-pronged incense burners: (13) Late Classic; deeply scored incense burner covers: (6) Late Classic.

JALAPA

No evidence of complex.

JUTIAPA

Asuncion Mita, Lot No. AM, from Group D, surface collection by G. Strömsvik (see also Note

101 and Figs. 101.3b, b', b''). Three-pronged incense burners: (3) Late Preclassic type (M).

PETEN

No evidence of complex. (A questionable incense-burner fragment with bifurcated protuberance but without smudging is illustrated by Ricketson and Ricketson 1937, Pl. 79d. from the Chicanel, Late Preclassic horizon).

PROGRESO

San Agustín Acasaguastlán, Lot No. E-183, from general excavation by A. L. Smith and A. V. Kidder (1943:143, Fig. 22a-f and Note 101). three-pronged incense burners: (7) Late Classic.

QUEZALTENANGO

Finca Arabia, Lot No. E-116, from surface collection by E. M. Shook. Three-pronged incense burners: (3) Late Classic type; deeply scored incense burner covers: (2) Late Classic type.

Finca El Paraíso, Lot Nos. R-1 and R-2, from surface collection and general excavation of mounds by E. M. Shook. Three-pronged incense burners: (8) Late Classic; deeply scored incense burner cover: (1) Late Classic.

SALCAJA

1. Lot No. N-1, from ancient pits in road cut between Salcaja and San Cristóbal Totonicapán, excavation by E. M. Shook. Three-pronged incense burner: (1) Late Preclassic (M); deeply scored incense burner covers: (2) Late Preclassic (M).

2. Robles collection, from east bank of Río Samalá (Fig. 1c-e). Three-pronged incense burners: (3) Late Classic type.

QUICHÉ

Zacualpa, Lot No. E-150, from Group A, central barranca, excavated by Robert Wauchope. Deeply scored incense burner cover: (1) Late Preclassic (M).

Chiche, see Note 101, surface collection by Robert Wauchope. Deeply scored incense burner covers: (2) Late Preclassic type (M).

RETALHULEU

No evidence of complex.

SACATEPEQUEZ

Sacatepequez site (near Santa María Cauque), Lot Nos. R-3, R-4a-d, from ancient pits along Roosevelt Highway, excavation by E. M. Shook. Three-pronged incense burners: (13) Early Preclassic (S); deeply scored incense burner covers: (20) Early Preclassic (S).

Chacaya, Lot No. C-68, from road cut on Roosevelt Highway 2 km southwest of Santiago Sacatepequez, excavation by E. M. Shook. Deeply scored incense burner cover: (1) Early Preclassic (S).

SAN MARCOS

La Unión, Lot No. K-22, from a gulley near government building, excavation by E. M. Shook. Three-pronged incense burner: (1) Late Classic.

Tajumulco, Lot No. K-21, from general excavation by B. P. Dutton and H. R. Hobbs (not illustrated in their publication). Three-pronged incense burners: (5) Late Classic.

SANTA ROSA

Finca El Progreso, Lot Nos. E-199 and E-199a and MN 1195 (Fig. 97.1a, b; Fig. 97.7a, a'; see also Note 101), from excavation for a drainage canal near finca house and surface collection from Terreno Dauro by Faustino Padilla. Three-pronged incense burners: (3) Early Preclassic type (CH).

SOLOLA

San Andrés Semetabaj, Lot Nos. E-10 and E-10b, from surface collections by E. M. Shook and S. F. de Borhegyi. Deeply scored incense burner covers: (4) Late Preclassic type (M).

SUCHITEPEQUEZ

Trapiche Grande, Coyotenango, Lot No. E-40, from surface collection by E. M. Shook (see also Note 101). Rim-head vessels: (4) Late Classic type.

TOTONICAPÁN

No evidence of complex.

ZACAPÁ

No evidence of complex.

It should be noted that the total count (Table 105.1) represents only the material stored in the Guatemala National Museum from sites that have

been investigated. Certain areas in Guatemala are archaeologically unexplored and our picture is therefore incomplete. Nevertheless, as can be seen in the total count, the vast majority of three-pronged incense burners with their deeply scored covers and rim-head vessels come from Kaminaljuyu during the early and Late Preclassic periods. It must not be forgotten, however, that Kaminaljuyu is the most thoroughly excavated archaeological site in the Guatemala highlands, and because of the great yield of pottery from all periods, the specimens relating to this complex are treated separately in the total counts. Strangely enough, throughout the careful and thorough excavations at Kaminaljuyu, no specimens of three-pronged incense burners, their covers, or rim-head vessels, appeared in the material after the Preclassic period. At sites other than Kaminaljuyu they appear occasionally in the Preclassic and in greater numbers in the Late Classic. No specimen of any kind has been excavated at any site of the Early Classic period (see Note 101). The picture presented by this evidence is too finely drawn to be a matter of coincidence.

It is tempting therefore to speculate on the possible reasons behind the appearance and disappearance of certain traits in this complex; and although a ready-made explanation is not at hand, a working hypothesis would be helpful, if not essential, for further study.

When the complex in its various forms and throughout its history is viewed pictorially on the map of Guatemala, it can be seen that the three-pronged incense burner must have been exclusively a highland trait at the time of its appearance in the Early Preclassic period. The relative abundance of the material at Kaminaljuyu suggests that this area may have been the scene of its birth. Here it was probably connected with a folk-cult related to the worship of fertility and rain. Characteristic of this early manifestation are the grotesque, bearded effigy prongs depicting individuals with tear streaks. In Note 97 I suggested that these prongs may represent the Kaminaljuyu rain god. In the Peten and on the Pacific coast this ceremonial complex was either unknown or avoided. At least, no evidence of it has been encountered in the collections made in these regions.

Sometime during the second half of the Preclassic period, the complex must have spread slowly to the east and to the west, eventually reaching as far as Salcaja and Asuncion Mita (see map). As the years passed, the three-pronged incense burners became more elaborate, the bearded faces on the prongs of the earlier types were replaced by grotesque, open-mouthed jaguars and other monsters on the body of

the censer, and plain prongs took the place of effigy prongs. It would seem, therefore, that they were used in the service of a larger pantheon.

The impetus behind the spread of the three-pronged incense burners is still in question. It could have been brought about by warfare and strife, by a peaceful movement of migratory groups, or, more likely, by a spiritual impulse in the form of a religious cult that radiated from a single source. If the latter is true, this source may have been Kaminaljuyu.

Why, then, did this religious cult, apparently so firmly established during the Preclassic, disappear during the succeeding Early Classic period? Probably new religious ideas from the northwest, in particular those from Teotihuacan, penetrated into the Guatemala highlands about this time and overshadowed or brought about the prohibition of earlier rites. Apparently at Kaminaljuyu and adjacent areas the complex came to an abrupt and final end. It is therefore curious to see the "renaissance" of three-pronged incense burners during the Late Classic period throughout the marginal areas, even as far as Chipoc in the Alta Verapaz, Quirigua in the Department of Izabal, and Copan in Honduras. The exception is again the Peten where they never were the mode. Such a "renaissance" could have occurred among conservative groups, less affected by the foreign religious ideas, or among others who discarded or revolted against them. In either case, the native folk cult must have remained in an "underground," existence throughout the Early Classic period. The Late Classic type of three pronged incense burner usually depicts animals or realistic, sometimes aged, individuals, and they frequently have moldmade features. From this we might suppose that the religious concepts of the Preclassic, with such frequent use of the grotesque, had been lost or definitely modified.

It is interesting that the rim-head vessels, quite frequent during the Late Preclassic period at Kaminaljuyu, disappeared there, to appear some 300 years later in the Late Classic on the Pacific coast. There they must have "monopolized" the region because no three-pronged incense burner seems to have crossed the boundaries. At present, there is no explanation for this curious situation. All that can be said is that they, like their "cousins," underwent similar stylistic alterations. They are also found in both human and animal form and frequently with moldmade features.

The renaissance of the complex was of short duration. New migratory groups claiming Mexican, and in particular Tula, origin appeared on the scene and must have brought it, together with the related religious ideas, to an end. For the middle of the

No. 106
December 1952

Notice to Replace Note 106

FORMERLY MAP OF THE RUINS OF MAYAPAN,
YUCATAN, MEXICO—*Morris R. Jones*

Since the issue of "Map of the Ruins of Mayapan, Yucatan, Mexico," by Morris R. Jones, as Note 106 (December 4, 1951), a new series of papers, *Current Reports*, has been initiated by this Department. These reports will deal at the outset largely with the results of field work at Mayapan. Constant reference will be made to the map of the ruins, which is, of course, an important document in support of the work there. It

consequently seems advisable that the map should become Current Report 1 of the new series.

Report 1 is a re-issue of the text of Note 106, which now becomes pages 2–5 of the new series, with the addition of an editor's note. It is requested that you destroy the old text pages and insert the present notice in their place. The map should be transferred to accompany the text of Current Report 1.

The Ruins of Cotio, Department of Guatemala, Guatemala

Edwin M. Shook

Throughout the Guatemala valley there are known at present over 50 scattered archaeological sites. The largest, Kaminaljuyu, on the southwest outskirts of Guatemala City, is more or less centrally located; spreading out in all directions from this great ceremonial center are others ranging in size from a single isolated mound to clusters of 20 or more. Surface collections of pottery from, and observations of, these valley sites strongly indicate that Kaminaljuyu was the seat of civic, cultural, and political power during the long Preclassic, Early Classic, and Late Classic periods. Thereafter all major activities apparently ended here and elsewhere in the valley. A lacuna exists in our knowledge of the area during the Early Postclassic period, suggesting that it may have been unoccupied or very sparsely populated. The final period before the Spanish conquest, the Late Postclassic, witnessed the growth of Chinautla, a site 2 km southwest of and above the modern town of the same name. Also, at this late date, throughout the Guatemala valley are indications of a thinly distributed population perhaps rural and engaged in subsistence agriculture.

Thus, by the close of the Late Classic period, the valley's long history as a center of major cultural influence in the highlands of Guatemala seems to have come to an end. Kaminaljuyu remained pre-eminent throughout but many small towns and villages flourished in the valley, undoubtedly under the jurisdiction of that center.

One of these ruined villages, Cotio, several kilometers west of Kaminaljuyu, is fairly typical of the

smaller Late Classic sites. It is located near the head of a deep southward-draining barranca (Fig. 107.1a) about 175 m south of Kilometer 13.3 on the newly constructed Pan-American or Roosevelt Highway running west from Guatemala City toward Mixco and the western highlands. The lands on which the ruins are situated pertain to the Aldea Cotio, in the municipality of Mixco, and have recently been subdivided for a real estate development called Colonia Roosevelt. A street branches off the highway and runs southward to the barranca head, passing the east edge of the Cotio ruins. I first visited the site April 23, 1950, before the destruction of its mounds began for the purpose of leveling and obtaining building material. Their complete obliteration within a short time appears certain, as has already happened, and continues to happen—to so many archaeological monuments near Guatemala City. It therefore seems worthwhile to record the ball court, two mounds, and a minor grave found at Cotio.

The ball court is a long rectangular enclosure with surrounding walls of even height (Fig. 107.1b). They maintain an elevation of 1.5 m above the level playing court and range above outside ground level from 1.5 m at the east to 2.5 m at the west end. This is due to the long east-west axis of the court being at right angles to the gentle westward slope of the terrain. The interior of the court has been cultivated for corn so that the original profile now has been lost. If there were side benches, they have long since been chopped away by the farmers hoe until almost vertical faces remain on all four

107.1. Ruins of Cotio, Guatemala: (a) sketch-map showing location of Cotio in the Guatemala valley between Guatemala City and Mixco; (b) sketch-plan of the ruins of Cotio.

sides, exposing a fill of mixed rubbishy topsoil and brown clay. No stones were used in the construction. Surfaces apparently had been faced with adobe plaster. This Cotio ball court, completely enclosed, is typical of 35 others in the Guatemala valley, 12 of which are in Kaminaljuyu.

Mound 1, squarish, flat-topped, and 2.25 m high, was built of the same material as the ball court and Mound 2. The only architectural features observable on the surface were lumps of burned adobe showing casts of small poles. These suggest that Mound 1 served as a substructure for a thatched roof building whose walls were of thin poles daubed with mud.

Mound 2, about 1.5 m high, was also flat on top and square in plan. Scattered on its surface and around its edges were chunks of burned adobe bearing small pole impressions.

Mound 3 (?). The ball court closes the north side of a miniature plaza on which face, from the east and west sides, Mounds 1 and 2. The plaza's south side now appears open, although here may formerly have been a third low platform mound. Intensive hoe cultivation in modern times has thoroughly disturbed the area. However, fragments of burned adobe from floor and wattle-and-daub wall construction, and a concentration of potsherds and obsidian chips, suggest the existence at one time of a small substructure.

The surface of the mounds, ball court, and surrounding terrain was littered with fragments of pottery and obsidian flake-blades; there were also pieces of a few manos, metates, and greenstone celts. None of the pottery observed on the site and in the small representative collection made and deposited in the Guatemala National Museum (Lot C-92) was older or younger than the Amatlé phase of the Late Classic period. Most of the sherds were of Amatlé hard wares: tall-necked jars; cylindrical vases; bowls with simple silhouette, simple silhouette with pedestal or annular base, and others with flaring rims. Also present were sherds of San José Plumbate cylindrical vases, of specular hematite Red-on-Brown cylinders, Red-on-Buff bowls, and Coarse Brown ware comales with high, straight-flaring walls. Several fragments of bail handles may have been from these comales.

Just west of the Cotio site begins a low area which drains southeast. Approximately 250 m from the ruins it drops off rapidly into a very deep barranca with almost vertical sides (Fig. 107.1a). Around the ravine's less abrupt slopes issue springs providing a year-round water supply for the local inhabitants and their stock. These springs had very likely also served the ancient people and may have been a factor which led to the settlement of Cotio.

Workmen, in April 1950, while digging topsoil, brown clay, volcanic ash, and underlying semi-solidified material (locally called *talpetate*), unexpectedly encountered on the north edge of the barranca the grave of a young (10–14 years) individual. The body lay on the floor of an intrusive pit about 2 m deep, which penetrated the surface soil, sterile brown clay, and volcanic ash, to the level of the *talpetate*. The grave furnishings included nine pottery vessels, a fragment of greenstone celt, and, according to the laborers, four highly polished stones, probably jade ornaments. The last were kept by the workmen; when I discovered the excavation, the broken vessels and celt fragment lay on the edge of the grave pit with scattered human bones and teeth. The vessels and celt were repaired and deposited as Lot C-93.

All nine pottery vessels appear to have been made of the same medium-textured, dark brick-red paste. Six are almost identical, small flatfish dishes of coarse unslipped, unpolished red ware (Fig. 107.2a). They range from 14.4 to 19.5 cm diameter, average 17.0 cm; from 3 to 4 cm high, average 3.5 cm; with walls consistently measuring 6 mm thick. These dishes were formed in a manner similar to the Coarse Brown ware shallow bowls of the preceding Early Classic Esperanza phase (Kidder, Jennings, and Shook 1946:206). The wet clay was pressed into a rough-surfaced mold, the marks of which remain on the bottom of each specimen. Only the two largest show a slight bending over the edges, simulating a rim. All have a flattish to rounded lip, unsmoothed exterior, cursorily smoothed unpolished interior to the lip's outer edge. The dishes were fired relatively hard. Surface color ranges from Munsell's 10R 4/4, 5/4, 4/6 to 5/6.

One bowl (Fig. 107.2b) of simple silhouette has a light brownish orange (5YR 6/6) slip on the exterior and over the lip to 5 mm down on the interior. The interior from this point nearly to the floor has a white (10YR 8/2) slip, carelessly applied, leaving horizontal streaks where the white is so thin that the reddish color of the paste shows through. Floor is unslipped, unpolished; slipped areas have low polish.

Figure 107.2c illustrates a deep bowl slipped red (10R 5/6 to 2.5YR 5/6) on the interior and down 3 cm on the outside. The remainder of the exterior bears the same streaky white as the former bowl. Also, as the white was either being applied or smoothed, it was smeared or stained by some of the red slip which adhered to the smoothing tool. The exterior and the upper half of the interior wall have a low polish.

The ninth vessel is a pedestal-base bowl (Fig. 107.2d). It has a slip, probably the same white as on the two just described, but in this case the firing

107.2. Pottery: (a) Four of six coarse redware dishes from grave at Cotio; these illustrate minimum and maximum size and range of form; (b) simple-silhouette white and light brownish orange; Cotio grave; (c) white and red vessel, Cotio grave; (d) specular hematite Red-on-White vessel, Cotio grave, diameter 19 cm; (e) White-on-Red-on-Orange pedestal-base bowl from Kaminaljuyu, Amatle phase; (f) White-on-Red-on-Orange pedestal-base bowl with hollow, closed bottom and punched-in rattles, Amatle phase; reportedly from Asuncion Mita, Dept. of Jutiapa, Guatemala.

produced colors ranging from white to orange 2.5YR 9/0; 7/6, 7/8 to 5YR 8/4). The slip covers the interior and the exterior to below the shoulder. Subsequently, specular hematite red (7.5R 3/6) was added in a single triangular area on the interior wall (half of this shown in hachure). The part of the bowl bearing slip took a low polish; the lower part of the exterior wall and pedestal base remained unslipped and unpolished red.

These nine vessels belong to the Late Classic Amatle phase of Kaminaljuyu and the Guatemala valley. This was proved not by the coarse red ware dishes which have not been identified previously in Amatle deposits, but by the three pieces last described. Sherds and vessels of the same ware and form as these have been recovered with other Amatle

107.3. Pottery: (a) bowl (Fig. 107.2e), painting by Antonio Tejada F; (b) bowl (Fig. 107.2f), painting by Antonio Tejada F; natural size.

material at Kaminaljuyu (Lots C-31 and C-38) and Amatitlan (Lot E-23). Another ware closely resembling and possibly identical to that of the bowls from the Cotio grave, varying principally in surface treatment, is White-on-Red-on-Orange or Orange-Red. Two examples are shown here, one from Kaminaljuyu and another reportedly from Asuncion Mita, Dept. of Jutiapa, in southeast Guatemala. The pedestal bowl (Lot C-13) from Kaminaljuyu (Figs. 107.2e; 107.3a) was collected with other Amatle specimens at a brickyard near Mound D-III-16, where workmen, digging earth and clay for brick making, tossed aside the pottery and artifacts encountered. This bowl has an all-over orange (5YR 6/6) slip except on the interior of the pedestal base. On the inner wall is painted a dark red band with four decorative elements in superimposed white. The slipped area has a low polish.

The example said to be from Asuncion Mita (Figs. 107.2f; 107.3b) now in the Guatemala National Museum (Cat. No. 1222) has an all-over orange-red (10R 5/6) slip, evenly smoothed and low polished. A specular hematite red band encircles the top of the interior wall, and four equally spaced vertical panels adorn the exterior wall. These are framed by heavy

white paint lines; the center of each panel is further ornamented with a design superimposed in white paint. This vessel has another feature relatively rare in Mesoamerica, a closed pedestal base, the sides of which are perforated with nine circular holes. These were punched through horizontally from the exterior after sealing the base, the clay pellets from the holes remaining inside as rattles.

The Cotio ruins are one of the many minor archaeological sites with ball courts in the Guatemala valley centering around Kaminaljuyu. The grave, although of an individual probably too young to have gained prominence in local affairs, was well stocked with offerings. It is our only example to date of the burial customs practiced at Kaminaljuyu and the immediate vicinity during the Amatlé phase.

A Possible Early Classic Site in Northern Yucatan

William R. Coe

While recently in Valladolid, I heard of the discovery of ruins near Colonia Yucatan, the center of the Yucatecan plywood industry. As they are in an area little known archaeologically, a visit promised to be of some value. The site is approximately 1.5 km south of Triplay, which in turn is said to be 31 km south of El Cuyo, a coastal port, and 48 km north of Tizimin. A good road connects all three points.

The five principal mounds constituting the site (though workers in the area report scattered, relatively insignificant mounds peripheral to the main group) are arranged as two parallel mounds to the north (the only ones considered here) and three others approximately 100 m to the south. There is some evidence that the intervening area was paved with small square cut stones. The group is uncleared but removal of surface rubble (perhaps a structure) for purposes of local road building has exposed in the north mounds an architecture somewhat unlike types usually found in adjacent areas. Unfortunately, only a brief study of the ruins was possible.

The removal of rubble towards the north end of one mound was sufficient to disclose the following distinctive elements: non-veneer masonry with a heavy smooth stucco overlay, inset corners, receding upper wall zones of a building or terrace which decidedly project beyond lower wall zones, and lower zones which appear to be set on a noticeable batter (Fig. 108.1). The corners of upper and especially lower wall zones are rounded. Moldings, other than the broad aprons formed by the upper wall zones, are absent as far as could be determined. No

ornamentation was found, but an exposed section in the other mound showed black and red striping on the lower wall zone of a buried structure, which, although there was little to go on, is identical perhaps in type to that just described.

If doorways, windows, or "vents" do exist, the visible sections fail to show them. Their absence, together with the quantity of surface rubble and the generally square plan of the structure, suggests that this was a substructure; resting on ground level, with a lower wall zone depth of about 1.5 m. This conjecture is very indefinite as exposures were relatively slight.

The traits associated with both Puuc and Mexican period architecture are almost surely absent here. Certain resemblances are noticeable in receding upper and lower wall zones of substructures between Colonia Yucatan and Uaxactun, Holmul, Naachtun, Calakmul, and La Muñeca. Inset corners of substructures are found at Coba, Piedras Negras, Tikal, Calakmul, Uaxactun, and elsewhere. The most apparent similarities, perhaps, are those found at Acanceh, particularly the large pyramidal substructure that stands just off the town's plaza. Andrews (1942:258) mentions that this structure contains rounded inset corners; and, from a photograph, it is further characterized by receding upper and lower zones of the apron type on the terrace walls (Fernandez 1947, Fig. 1).

With due regard to the inadequacy of information on Colonia Yucatan, about all one can say is that its architecture suggests stylistic and perhaps

108.1. Early Classic site in northern Yucatan: (a) ground plan and elevation of structure principally described; (b) north-east corner; (c) southeast corner.

temporal affiliation with Classic sites in both central and northern areas. If there is any truth in this, the Colonia Yucatan material may possibly represent a northern Early Classic site far closer in type to Acanceh, thought by many probably to be Early Classic, than, say, to the pre-Puuc architecture of Oxkintok (Shook 1940:168–69, Fig. 3). It is worth noting that Acanceh, on ceramic evidence, was occupied in Late Formative times (Brainerd 1951).

Though the evidence is admittedly shaky, Colonia Yucatan, as now exposed, does seem, to represent an Early Classic site of the northern area. Two distinct types of architecture may have co-existed in this area during Early Classic times, namely,

that represented by Colonia Yucatan and, perhaps, Acanceh in the northern and central parts, and bar Oxkintok in the west. During Late Classic times, the former style may possibly have perpetuated itself at Coba, to be superseded by the East Coast style; that of pre-Puuc Oxkintok clearly eventuated in typical Puuc architecture.

A superficial surface search for sherds revealed none. Needless to say, a conclusive find of a basal-flanged bowl would have been quite welcome.

Measurements in this paper are approximately correct; orientation was obtained with a simple but reliable pocket compass. "Stick" in Figure 108.1b, c is one-half meter.

PHILADELPHIA, PA.

Waxen Idols and a Sacrificial Rite on the Lacandon

J. Eric S. Thompson

In documents referring to a little-known entrada, under the leadership of Juan de Morales Villa Vicencio, into Lacandon territory in 1586, published in *Boletín del Archivo General del Gobierno* (Reducción 1937), there are interesting references to the use of waxen idols by the Lacandon. These are the only references which I know to this custom among the lowland Maya of the sixteenth century, although the high ceremonial importance of black candles of native beeswax, as compared with those of white wax sold commercially, would indicate an important use of beeswax in prehispanic ceremony.

After the inglorious retirement of Villa Vicencio's army, baffled by the Fabian tactics of its Lacandon opponents, who, as usual, refused to engage in regular battle, a small group was sent to observe what signs of activity there might be around the lake (Miramar?) on which the island fortress had stood. The group had orders to return with tangible evidence that they had carried out their orders, and one of the things they brought back was this idol of wax. In the deposition of the scribe the package is described as "a bundle of pine torches tied up, and with a small idol of wax on top, of the kind which the Lacandon make for their sacrifices." In the testimony of the Bachajon leader, from Jujuicapa, the waxen idol becomes plain wax but is still on top of the bundle of pitch pine, and the whole had been placed on the ground in an open area close to the lake. There are printing errors in this series of reports, and it is not unlikely that the scribe, Gaspar de Molina, might have dropped words. Accordingly, little importance

attaches to the absence of the words "*el idolillo de*." Two of his assistants from the same village (also spelled Xuxueapa), in a point deposition, describe the finding of the bundle of pine torches "with the little idol of wax which was placed upright on the ground." The last could refer either to the bundle of tea, or to the idol, or to both.

The testimony of Anton Gomez, leader of the detachment from Ocosingo, is more explicit: "Close to where the canoes were kept [*el estero de las canoas*] they found the bundle of pine torches with the little idol of wax and rubber, and it seemed to him that it had been placed there only a short while before, because it was new and did not seem to have been rained on." In answer to questions he continued that "it seems that [the offering] signifies that it had been offered to the demon so that he would obstruct the road should the Spaniards pass over it again, and their [the other objects] signify the difficulties in which they [the Lacandon] find themselves, because the pot for [of?] maize, which was next to it signifies hunger, and the hairs stuck in the said wax signify the number of men whom they have killed. And this he understands according to their ancient rites as a man who grew up among them [*ellas* misprint for *ellos*?]."

Apart from the introduction of rubber as a component of the little idol, the testimony of Anton Gomez is of interest because of his statement that he grew up amid paganism. He declared his age to be fifty-five, and in that connection it is interesting to remember that following the capture of Pochutla in 1559, Lacandon from there had been settled at

Ocosingo in 1564. Accordingly, he may have been a christianized Lacandon and well acquainted with their rites. On the other hand, there may not have been much difference between pagan Tzeltal and Lacandon in such matters.

Two other Indians of Ocosingo were witnesses in a point deposition to the finding of the bundle of pine torches "*con el idolillo e hule*." Here *e* might be need incorrectly as a conjunction before *hule*, or it might be a misprint for *y* or for *de*. The employment of rubber in the making of idols is well known. Indeed, idols partially of rubber have been dredged from the sacred cenote at Chichen Itza.

In this same series of papers dealing with this 1586 entrada of Villa Vicencio there is mention of an unusual rite. During the pursuit of the Lacandon, there was found on the road a place for sacrifices together with the body of a boy of about five years of age. He had had his breast cut open down to the middle, and it seemed that his heart had been removed through that opening. "His right foot and his feet [sic] had been burned, and he had three wounds, as though made with lance thrusts, in his right foot, and the left arm stripped entirely of flesh from wrist to elbow, and with the bones of the arm stinking out (*las canillas de fuera*)." The boy was a Christian child, son of a *vecino*, who had been captured by Lacandon in some previous raid.

On another occasion members of the expedition found the desecrated grave of a certain Monterrey, who had been killed shortly before with a stone hurled down on him by a Lacandon. The Lacandon had broken a cross put over the grave, and with that they had dug up Monterrey's body, and had removed all the flesh of the left arm from wrist to

elbow. The removal is said to have been the same as in the case of the child.

One body was that of an enemy slain in battle, and the other that of a youthful prisoner taken after a raid on the enemy. It would seem, then, that the removal of the flesh from the left arm represents some magical rite to bring victory. Conceivably, the eating of the flesh of the left forearm, used in war to carry the shield, made the enemy lose his ability to defend himself, or gave to the eaters increased defensive abilities. In that connection it is worth bearing in mind that Aztec warriors sought the middle finger of the left hand of a woman who had died in childbirth; with such or the woman's hair placed in his shield, he had greater courage, and no one would succeed in taking him prisoner. The left arm and hand of a woman that died in childbirth was sought by robbers, for it would take away all courage from the lawful owners of a house so that they would not resist when the robbers entered with such an arm. The point in these cases is that in Aztec eyes a woman who died in childbirth was a warrior; she shared the daily task of accompanying the sun with the souls of male warriors, and she may be represented with shield and weapons. Accordingly, she used her left arm to carry her shield. It will be remembered that the Aztec goddess Ciuacoatl always carries a shield.

Obviously, this Lacandon rite is not directly comparable to the preparation of trophies, the enemy's jawbone or other bones, as described by Bishop de Landa, but it is of interest to note that the jawbone of the dead enemy was worn on the arm. It is possible that these jawbones were not only trophies but had magical powers to help their wearers in battle.

The Introduction of Puuc Style of Dating at Yaxchilan

J. Eric S. Thompson

In a study of dating which yields a month coefficient of a Calendar Round date one less than in the normal system (e.g., 1 Kan 1 Pop in place of the normal 1 Kan 2 Pop) it was noted that this style is followed on two monuments at Yaxchilan (Note 79). To describe that system of dating the term Puuc way suggested because from present evidence the style is most prevalent in that area, and possibly originated there. At least, the earliest known examples (9.12.0.0.0 and 9.13.0.0.0) are on monuments at the Puuc site of Edzna.

The two monuments at Yaxchilan with Puuc-style dates are Stelae 18 and 20, and in the paper cited the senior author noted that both monuments have certain stylistic affinities with Campeche and Yucatan.

Many years ago Teeple showed that the introduction of a new method of recording lunar data was marked at Piedras Negras, Naranjo, and perhaps Yaxchilan by recording on different stelae the lunar calculations for a given date in both the new and the old system. The purpose of this paper is to examine evidence for analogous double dating at Yaxchilan to record the intrusion of the Puuc system at that site.

Stela 18, Yaxchilan, carries the date 3 Eb 14 Mol, a clear example of the Puuc system. The middle and right dots of the day coefficient are how somewhat irregularly shaped, but that all three are numerical is not, I believe, open to serious question. Indeed, Bowditch (1901:2:19) and Morley (1938:2:34), who had no axes to grind, read the coefficient as 3, although they wrongly identify the day as Cimi.

At Y5-X6 of the upper step of the southeast doorway of Structure 44, Yaxchilan, there is a date which is quite clearly 2 Chuen 14 Mol, and which almost certainly has the Long Count position 9.14.16:15.11 2 Chuen 14 Mol (Note 71). This date is one day before that on Stela 18:

Standard System		Puuc System
Str. 44 (9.14.16.15.11)	2 Chuen 14 Mol	(2 Chuen 13 Mol)
(1)		
Str. 18 (9.14.16.15.12)	3 Eb 15 Mol	3 Eb 14 Mol

Data in parentheses are supplied. Although the Long Count position of 2 Chuen 14 Mol is reasonably secure, that of 3 Eb 14 Mol is open to question. Miss Proskouriakoff (1950:198) dates Stela 18 by trait incidence at 9.16.14.0.0 plus or minus two katuns. It is, however, well known that there is a tendency at several Maya cities to inscribe important dates on monuments erected from one to three katuns later. Thus the date 9.14.16.15.12 3 Eb 14 Mol might have been carved on a monument erected at: 9.16.0.0.0 or 9.17.0.0.0, particularly if it had the important role of marking the introduction of the short-lived system of Puuc dating at Yaxchilan.

However, the association of the date on Stela 18 with that in Structure 44 rests on far stronger evidence than the fact that they represent sequent days in the two systems. Each date is followed by six identical glyphs, only one of which occurs in any other text at Yaxchilan, although in most cases the main elements are not uncommon at Yaxchilan and

elsewhere. The glyph found on other monuments is the first of the six, and follows immediately 14 Mol in both texts. The main sign is the burden element, to which are attached the comb and lunar affixes as postfixes. The compound, which also occurs in the codices, commonly follows Calendar Round dates at Yaxchilan, and probably means the charge (fortune or burden) of the count. That the comb here, as elsewhere, has the value *xoc*, "count," is shown by the fact that at L'3 on Lintel 33 a head, almost surely that of the *xoc* fish, replaces the comb in the same compound.

The following five glyphs form clauses similar in sequence and in every essential on Stela 18 and the step of Structure 44 (Figs. 110.1.1, 110.1.2). They are: jade glyph with unusual prefix, "Chuen," hatched spot with death manikin prefix, Mol with unusual postfix which includes an inverted Ahau, and Ben-Ich Zotz' with comb and flared tau postfixes. All five main elements occur elsewhere at Yaxchilan, but none of them is common, and they are never found with the same affixes or associated with one another. Whereas there are clauses which are repeated time after time at Yaxchilan, there does not seem to be any other clause at that site which appears only twice. Accordingly, the presence of this clause with its unusual component glyphs with only these two dates greatly strengthens the probability that the dates are intimately related and, accordingly, treat of the shift to the Puuc system. As the shift is presumably marked by sequent logs falling on 14 Mol, it is interesting to note the presence of a Mol sign in the accompanying clauses. The Mol element is not uncommon, but nowhere else at Yaxchilan or at other sites (Palenque, Copan, Quirigua), the glyphs of which have been indexed for my glyph dictionary, is it supplied with the same unusual postfixes. One might hazard, purely as a speculation, that this Mol compound in some way declares that the shift is in that month. So far as I know, the month sign Mol nowhere appears with a single circle in the center; it normally has the twin jade-bead symbol there. Nevertheless, there is ample evidence that the two elements are interchangeable (e.g., in the Muluc glyph).

The second Puuc style date at Yaxchilan is 6 Ix 16 Kankin recorded on Stela 24. It cannot be matched by the previous day in the standard system, as was the case with 3 Eb 14 Mol, but it is related to a date which appears twice in that same Structure 44, namely 9.14.1.17.14 5 Ix 17 Kankin. This latter date is given as a much damaged Initial Series on Lintel 46, which spans the northwest doorway of Structure 44, and it is also reached by calculation (the date itself is not now visible, although it probably is hidden

under masonry at X1-Y1) an the same upper step of the southeast doorway of this same structure. Indeed, it is connected with the date 2 Chuen 14 Mol by a distance number:

(X1-Y1)	(9.14.1.17.14	5 Ix 17 Kankin)
Y4-Y5	15.15.17	Count forward to
Y5-X6	(9.14.16.15.11)	2 Chuen 14 Mol

Morley (1938:2:428, 455) follows Bowditch in identifying the month sign of Lintel 46 as Mac, and then accepts that of Stela 20 as also Mae because of its resemblance to that of Lintel 46. Nevertheless, there can be no doubt that in both cases the personified form of Kankin is depicted. This is proved by the suffixes which in both cases are the "*ak*" element. This is always postfixed to Kankin, but never to Mac. Furthermore, the absence of the "down-ball" affix which is always a prefix or infix of Mac is evidence that these signs can not be those of Mac (Thompson, 1950, Fig. 18). That these signs are Kankin is beyond reasonable doubt, but even were they Mac, the relationship between the two dates would remain the same, for that of Stela 20 in the Puuc system is just 40 vague years after, or 12 vague years before, the date of Structure 44:

(9.14.1.17.14)	5 Ix 17 Kankin
2.0.10.0	(40 × 365)
(9.16.2.9.14)	6 Ix 16 Kankin (17 Kankin in normal system)

In this case, too, unusual explanatory glyphs indicate that the two dates are linked, for the two passages in Structure 44 which treat of 5 Ix 17 Kankin and the passage on Stela 20 which treats of 6 Ix 16 Kankin share a two-glyph clause found nowhere else at Yaxchilan (Figs. 110.1.3–110.1.5). This consists of expiration (or its personified form, the death manikin), Kan cross te (2) and a lunar glyph with an unusual prefix which is commonly found as the postfix of Kayab. The Kan cross compound occurs in a few other texts at Yaxchilan, but in no other case followed by this lunar compound, which, in fact, does not appear elsewhere at Yaxchilan, and. I have not encountered it at Copan, Palenque, or Quirigua.

It is possible that a third glyph belongs in this clause. In the two texts of Structure 44 this two-glyph clause is followed by a most unusual cauac and Ben-Ich winged cauac compound. Unfortunately, the corresponding glyph block of Stela 20 is damaged. The outlines of two elements are recognizable, and both show the characteristic frame of the cauac element, but there is certainly, no Ben-Ich prefix. The

110.1. Hieroglyphic clauses at Yaxchilan.

wing is also absent, but that is probably not of significance. What remains of the interior of the main element rather suggests the caban sign, which has the same asymmetrical frame as cauac, and in weathered examples is hard to distinguish from cauac. It is possible, but far from certain, that this damaged glyph on Stela 20 is a variant of the cauac compound found in Structure 44. Should that be the case, the clause shared by these three texts would consist of three unusual glyphs.

As to the meaning of these glyphs we must remain in the dark for the present. The lunar glyph might refer to a lunar calculation, beat one must

remember that it frequently has a derived meaning, that of a possessive, for in Yucatec a means both moon and possession. Cauac compounds are extremely common in Maya texts, but nowhere else at Yaxchilan, nor in Copan, Quirigua, Palenque and codical texts, is it found with a Ben Ich prefix. There is evidence on Copan U that the regular tun sign could be used also to record the 365-day year, and that raises the possibility of these cause compounds having a similar extended usage.

The shift to the Puuc system, of course, involves the 365-day year and the year bearers, but one may wonder why a gap of 40 years of 365 days exists

between the two records (a backward shift of 12 years seems less probable). One must count forward 40 years (or back 12) to advance the coefficient of the same day sign on the same month position by one. This is the "foot" of the round of the vague year functionally corresponding to the foot of the year of the Jacalteca (La Farge and Byers 1931:158) and to the apparent foot of the katun (Thompson 1950:248). The text of Stela 20 may therefore be intended to record that after 40 vague years, the foot of the vague-year round, a date which has been changed to the Puuc system will show an increase of one in the day coefficient and a decrease of one in the month coefficient. This is just the kind of numerological juggling which seems to have preoccupied the Maya. Whether that is the true explanation or not, I think that the 5 Ix 17 Kankin and 6 Ix 16 Kankin dates are deliberately associated, both because of the explanatory clause with all three entries and because the first of the pair is linked to the first of the 14 Mol pair by a distance number orb the step of Structure 44.

I have previously suggested that Structure 44 was probably dedicated at 9.15.0.0.0, and that dating is preferred by Miss Proskouriakoff (1950:234). If that is so, and if the Long Count position of the date on Stela 20 is 9.16.2.9.14 6 Ix 16 Kankin and was not far in the future when the monument was erected, it follows that a katun must have elapsed between the carving of the long texts of Structure 44 and the short one of Stela 20. However, if the Mol compound and the cauac compound do refer to a shift to the Puuc system, the texts of Structure 44, Stela 20, and Stela 18 must have been carved or, at least, planned about the same time, otherwise there would be no purpose in recording these clauses with dates in the normal style. Unless we can assume that texts on monuments were planned a katun or more in advance, the presumed interval between the erection of Structure 44 and the two stelae, Miss Proskouriakoff has trait

differences which call for it, would be a strong argument against the very tentative meanings suggested for those two explanatory glyphs; it would not invalidate the thesis that the texts together mark by old and new entries the short-lived shift to the Puuc system.

An interesting feature of the text of Stela 18 is the presence at E2 of a glyph not found elsewhere at Yaxchilan, nor at Palenque, Copan, or Quirigua, but which is quite common at Piedras Negras. This stela then hints at new ideas reaching Yaxchilan not only from the Puuc country, but also from Piedras Negras. At about the same time another Piedras Negras glyph makes its appearance at Palenque. There is, therefore, some evidence of an intellectual exchange of ideas in the Usumacinta Chiapas region about this time. As compilation of the dictionary of Maya glyphs advances, such interchanges will be more readily detected.

The shift to the Puuc system of dating was short-lived at Yaxchilan, as were Yucatecan and Campechan influences on sculpture. The causes for their acceptance and subsequent rejection are mysteries; their solution should throw light on inter-city relations during the Classic period.

HIEROGLYPHIC CLAUSES AT YAXCHILAN

110.1.1. Southeast doorway, Structure 44, X6-Y7.

With date (9.14.16.15.11) 2 Chuen 14 Mol.

110.1.2. Stela 18, A4-A8. With date (9.14.16.15.12) 3 Eb 14 Mol.

110.1.3. Lintel 46, Structure 44, F'3-G'4. With date 9.14.1.17.14 5 Ix 17 Kankin.

110.1.4. Southeast doorway, Structure 44, X2-Y2.

With missing date (9.14.1.17.14) 5 Ix 17 Kankin.

110.1.5. Stela 20, E3-E7. With date (9.16.2.9.14) 6 Ix 16 Kankin.

Zutugil Dugout Canoes

Samuel K. Lothrop

Some time ago we published a brief account of the unique type of dugout canoes employed by the Quiche, Cakchiquel, and Zutugil Indians who dwell on the shores of Lake Atitlan, Guatemala (Lothrop 1929). Several years later, while dwelling in the town of Santiago Atitlan and excavating in the vicinity for the Carnegie Institution of Washington, we chartered one of these vessels to transport our men from the town to the various places where we worked. Although we used an outboard motor, which more than doubled her speed even with a dozen people on board, there were various occasions when the motor failed to function and our men paddled the canoe in their usual fashion in all kinds of weather.

Lake Atitlan is 1550 m. above sea level. It measures about 40 km from east to west and 16 km from north to south. On the south side are two great volcanoes; on the other three sides are steep cliffs well over 300 m high. Most navigation is at night as almost every afternoon there are strong winds known as *chocomil* and *panumul*, and the gales known as northers may blow for days at a time and no native ventures offshore (McBryde 1933:71, 76). Santiago Atitlan and the other towns on the south shore of the lake are located on more or less sheltered harbors but even the largest canoes might be weatherbound. Not only does the lake get rough but the surrounding topography causes sudden and erratic gusts which may swing a canoe broadside into the trough of the waves. These conditions call for sturdy vessels and expert watermanship. Lake Atitlan is as much as 300 m deep, and, owing to its precipitous shores, one

would not expect reefs to add to the perils of navigation. Off Cerro de Oro, however, we hit one, of which the men on board had no previous knowledge.

Atitlan canoes are paddled exclusively by the men, who always stand erect, regardless of the size of their barque (Fig. 111.1b, d). This method of paddling was noted in 1586 on Fonseca Bay by Ciudad Real (San Juan and Ciudad Real 1873:1:376). As his crews came either from Nacaome in Honduras or from Isla Teca, they probably are Choluteca Indians. When we first crossed this bay we photographed a boat rowed by a crew standing erect, perhaps a survival of the ancient method of paddling (Lothrop 1926:1, Fig. 7).

The Zutugil women spent many hours in Lake Atitlan washing their clothes and their hair; and as children they learn to swim. The men never wash in the lake but in small sweat houses. Hence, like the sea-faring Yahgan men of Tierra del Fuego, they do not learn to swim. When sober, the Zutugil men are excellent watermen, but all too often they start home drunk from their principal market at Solola on the north shore. Embarking in calm waters under the shelter of the cliffs, they encounter high seas in the middle of the lake. If the canoe broaches to and is capsized, the crew may drown. If the bodies are not recovered, the family and friends hold a wailing ceremony on the edge of the lake (Fig. 111.2c). This happened at least twice during our period in residence at Santiago Atitlan.

The Zutugil canoes are dugouts of cedar with raised wash-boards of pine. The largest canoe we saw belonged to the municipality of Santiago Atitlan

111.1. Tzutuhil dugout canoes: (a) repairing the dugout of Pedro Mendoza at Santiago Atitlan; (b) the same dugout, equipped with an outboard motor, off Tzanjayam peninsula; (c) miscellaneous dugouts on the north beach at Santiago Atitlan; (d) the municipal dugout of San Pedro Laguna.

and had been built several years prior to 1928, when A. V. Kidder, G. C. Vaillant, and I traveled in it (Fig. 111.2b–d). It was 10.7 m long and 1.6 m broad. It was still in existence in 1932 but had been replaced before 1936 by one measuring 10.05 m by 1.06 m (McBryde 1947:99, Pl. 24). In 1932 the municipality of San Pedro Laguna also owned a large dugout (Figs. 111.1d; 111.2a). A small canoe we measured was 3.7 m long and 66 cm wide. Some are even smaller (Fig. 111.1b, background). These small canoes are used principally by farmers to reach their lands inside Santiago harbor but some of them venture across the lake. Most drownings happen from this class of vessel.

Santiago Atitlan has by far the largest fleet on the lake. McBryde (1947:99) estimates that there were over 250 canoes at this town in 1936 and states that most of the other canoes on the lake had been built there. We may note that in 1524, when Pedro de Alvarado (1924:71) conquered the Zutugil, his Cakchiquel allies produced over 300 canoes.

The boat we chartered, at \$6.67 a month, may be regarded as a typical lake-going canoe of moderate

dimensions. We took more than 50 measurements on her hull so the plan in Figure 111.3 should be reasonably accurate. She also appears in Figure 111.1a, b. Her length was 5.8 m and her beam was 1.2 m. The owner, Pedro Mendoza, an intelligent Indian, one of the few who could read and write Spanish, was our next-door neighbor and friend.

The wood for the hull, we were told, was from a cedar tree cut near the top of San Pedro volcano, across the harbor from Santiago Atitlan (Fig. 111.2a, background). As shown in Figure 111.3c, the bottom of the feel-less hull came from the greatest diameter of the tree. This insured maximum buoyancy; the insloping sides increased stability and made the boat drier in rough weather.

Such tumble-home sides were common on European sailing ships for several centuries, especially on men-of-war which carried heavy cannon as far above the water as possible. It is a sporadic trait in the New World. The barques in which Alonso Ponce crossed Fonseca Bay measured 1.37 m across the bottom but narrowed to little over two palms' width at

111.2. Tzutuhil dugout canoes: (a) San Pedro Laguna dugout leaving Santiago Atitlan; (b, d) the municipal dugout of Santiago Atitlan in 1928; photos from Museum of the American Indian, Heye Foundation; (c) wailing ceremony on the beach at Santiago Atitlan.

the gunwale (San Juan and Ciudad Real 1873:1:375–376). The Timbu Indians of the lower Parana had a tumble-home which narrowed the forward half of their dugouts in equally extreme fashion (Marquez Miranda 1930:70, Lam. I). Outrigger canoes in the Pacific often have tumble-home sides (Mitman 1923, Fig. 94).

The hulls of Atitlan dugouts have two features we have not seen elsewhere. One is the flat V-shape bows (Fig. 111.1c). In ordinary use, unless the canoe is heavily loaded, this element is entirely above water (Fig. 111.1b), but when paddled into a heavy sea these bows give added buoyancy forward. Another unusual characteristic is the handles, which are not inset but are cut from the same piece of wood as the hull itself. All canoes have a pair at the stern; the larger vessels have an additional one at the bow. They are used to beach the vessel. The dugout in Figure 111.3 did not in fact have a bow handle, but

we have added one as it appeared on another of the same size.

Apart from the flat bows and square sterns, Atitlan hulls are rounded with relatively flat bottoms. There is a slight sheer at the bow and stern, partly concealed by the straight edge of the gunwale. The ideal thickness of the hull is shown in Figure 111.3d. Point A should be one finger thick; point B two fingers, and C, the bottom, should be three fingers in thickness.

It will be noted in Figure 111.3a that the greatest beam is just behind the bows. This indicates that the bow end of the tree was nearest the ground and the hull tapers as did the tree trunk. This results in a partially streamlined hull. With only one or two people on board and propelled by a small outboard motor, this massive vessel rode high in the water and was surprisingly fast. At half-throttle, we could cover the 16 km to San Lucas Toliman in an hour.

111.3. Tzutuhil dugout canoes: scale plans of a Zutugil dugout from Santiago Atitlan. Note: All photos not otherwise acknowledged are from Carnegie Institution of Washington, Department of Archaeology.

An unusual feature of Atitlan dugouts is the presence of washboards from 15 to 38 cm wide and about 2.5 cm thick. They are sawed pine planks secured with nails. The seams are filled with pitch. Although the boat is protected by up-sloping washboards, we shipped a good deal of water in rough weather.

Inasmuch as the entire construction is done with ordinary carpenter's tools and the washboards are nailed in place, they should perhaps be regarded as a European innovation. This is not necessarily so. As Dixon (1928:196) points out, dugouts with raised sides were manufactured by the interior Athabascan tribes of British Columbia and Alaska as well as by the Carib of Venezuela and the Antilles. They also were known on pre-Spanish balsas of the Peruvian coast and present-day balsas on Lake Titicaca (Lothrop 1932, Pl. Xvii, b; Xviii, d). Some of the canoes shown in Maya codices and frescoes have bows and sterns raised so high that it is scarcely possible that they were carved from the same tree as the hull (Thompson, 1949:70).

The Atitlan dugouts have no interior fittings. There are neither seats, thwarts, nor braces. Sometimes a little straw is spread on the bottom for the

convenience of passengers (Fig. 111.2d), but this is a doubtful asset as it usually houses a colony of fleas. The equipment consists of gourds for bailing and paddles, which may number from one to eight. We have never seen an Indian use a sail, in spite of the fact that a few local ladinos have sailboats (Fig. 111.2c). Our outboard motor, probe first ever seen on an Atitlan dugout, aroused little interest except among our workmen who, without it, would have had several hours of hard paddling daily.

Atitlan canoes must be sturdy to survive, for they encounter rough water and rocky shores. It is not uncommon for the hull to split. In that case the hull is turned bottom up on the beach and the leak is plugged with tar (Fig. 111.1a). An interior batten may be nailed over the crack.

The owner of the dugout we chartered used the following Zutugil terms to describe his vessel:

dugout canoe: <i>jukúa</i>	bow: <i>rutzám jukúa</i>
hull: <i>canoj</i> (Sp.)	stern handle: <i>jári rechajukúa</i>
gunwale: <i>ruchi jukúa</i>	bow handle: <i>jári rutzamjukúa</i>
stern: <i>rechajukúa</i>	paddle: <i>tzaj</i>

The Survival of the Maya Tun Count in Colonial Times

Tatiana Proskouriakoff

On pages 124 and 125 of the Codex Perez, now in the possession of the Escalante family of Merida, Yucatan, there is a table which consists of a list of 17 Christian years beginning with 1758, correlated with data of the Maya calendar. This table, as it is reproduced on pages 246 and 247 of the translation of the

codex by Dr. Ermilo Solis Alcala, differs in important particulars from a photographic copy of the original obtained for the Carnegie Institution of Washington by Sylvanus G. Morley in 1936. The following is transcribed from the photographic facsimile (tz' is substituted for the inverted c of the original):

1758	Bolon muluc	1 pop	9-3	9 hiix	16 Zec
1759	Lahun hiix	1 pop	10-4	10 men	11 Zec
1760	Buluc cauac	1 pop	11-5	11 cib	6 Zec
1761	Lahca kan	1 pop	12-6	12 Caban	2 Zec
1762	Oxlahun muluc	1 pop	13-7	13 Etz'nab	16 Zootz'
1763	Hunil hiix	1 pop	1-8	2 ahau	6 Zootz'
1764	Cabil cauac	1 pop	2-9	3 imix	2 Zootz'
1765	Oxil kan	1 pop	3-10	4 Yk	(16) Zip
1766	Canil muluc	1 pop	4-11	5 Akbal	(11 Zip)
1767	Hoil hiix	1 pop	5-12	6 kan	6 Zip
1768	Uacil cauac	1 pop	6-13	7 Chicchan	(1) Zip
1769	Uucil kan	1 pop	7-1	8 Cimi	16 Uoo
1770	Uaxac muluc	1 pop	8-2	9 Manik	10 Uoo
1771	Bolon hiiz	1 pop	9-3	10 amat	6 Uoo
1772	Lahun cauac	1 pop	10-4	11 Muluc	7 Uoo
1773	Buluc kan	1 pop	11-5	12 Oc	(16) pop
1774	Lahca muluc	1 pop	12-6	13 Chuen	(11) pop
(1775)	Oxlahun hiix	1 pop	13-7	1 Eb	6 pop)
(1776)	Hunil cauac	1 pop	1-8	2 Ben	1 pop)

The entries in parentheses have been added by the author. In the Solis Alcala transcription, the table begins with 179, nine years earlier, and in the last two columns, 1 Cauac and 11 Zootz' are interpolated opposite the year 1763, moving the remainder of the entries one year down in the table. The last entries, 13 Chuen and (11) pop, are omitted. Apparently this is an attempt on the part of the translator to correct errors and omissions which he attributes to the copyist. Here, however, we follow the copy made by Perez, since there may be significance in the fact that his table does not extend over a complete katun, and since even its internal discrepancies may be useful in furnishing clues as to the manner of its construction.

The first two columns of the table give a correlation between Maya and Christian years. Such correlations occur in various native sources, but do not all agree. Nor do separate dates given for events always give the same correlation. This particular one, however, occurs repeatedly in independent parts of the Perez codex and in the Tizimin, and is one which many scholars accept as correct. It is perfectly regular, and if we extend it back into the sixteenth century, the year 1553 will be correlative with the year 12 Kan, Landa's "typical year," which he shows beginning on July 16.

On page 66 of the Chronicle of Oxkutzcab, which forms the basis of Thompson's correlation of Maya and Christian chronology, is given a similar year table, which, if extended, places the year 12 Kan opposite 1554. Thompson considers this displacement, however, as due to a difference in notation, and explains that in this chronicle the Maya year is placed next to the year in which it ended (Thompson 1927). If this is true, the discrepancy between the two tables involves no discontinuity in the actual count of years.

After the year bearers in the Perez table, we are given the coefficients of the days that begin Pop and Uo in each year. The sign Ahau, which follows, is repeated without coefficients. The next column seems to consist of consecutive days, beginning with 9 Ix. 1 Cauac, which would normally fall between 13 Etz'nab and 2 Ahau, is omitted, but though all subsequent days are moved up in relation to the years, their correlation with the last column remains intact, for in this column there is a similar omission. The function of the column of days in the table is not clear to me. There may be some significance in the fact that the 2 Ahau of this series is a tun ending. In the year 1 Ix, with which it occurs, it would fall on 7 Zotz', one day after the entry in the last column. Moreover, as we shall see, its coefficient, 2, is the same as that of the expected katun.

Although the last column contains many irregularities, its general pattern is that of month positions at tun intervals, and we surmise that these month positions are the positions of Cauac, the last or penultimate day of the tun, the day preceding the tun Ahau. It is surprising to find a list of tun endings recorded as late as 1774, when there was apparently already much confusion as to the length of the katun and the mechanics of its count. Offhand, one might suppose that this list was copied at random from some earlier manuscript. This cannot be the case, however, for it is in as perfect concordance with the earlier record on page 66 of the Chronicle of Oxkutzcab as the irregularities and errors in both texts allow.

Ignoring these irregularities for the moment, we note that the last four tun endings given in the Oxkutzcab table run in perfect sequence:

1542	13 Kan on Pop 1	5 Ahau on 16 Tzec
1543	1 Muluc on Pop 1	1 Ahau (the tun) on 11 Tzec
1544	2 Ix on Pop 1	10 Ahau on 6 Tzec
1545	13 Cauac on Pop 1	6 Ahau the tun on 1 Tzec

In this case also, the month positions given are those normally associated with the day Cauac preceding the Ahau of the tun. Nevertheless, there is essential agreement between the tun end and the year in which it occurs. Thus, for example, in the year 13 Kan, 16 Tzec would be 4 cauac, and the next day, 5 Ahau, is designated as the tun. In the following year, the tun ends five days earlier, on 11 Tzec, which is 13 cauac, the day before 1 Ahau. Since 73 tuns are exactly equal to 72 Maya years, after the lapse of such a period, the end of the tun will return to the same month position. If in 1542 it was on 16 Tzec, 72 years later, in 1614 it would be again on 16 Tzec, and again in 1686, and in 1756. In perfect agreement with this, the Perez table gives 16 Tzec as the tun ending for 1758, and continues the count in regular sequence for four more tuns except for 2 Tzec in place of 1 Tzec. These first five tuns must have been calculated in some such way from an earlier record, for if they are month positions of Cauac, each falls, not in the Maya year with which it is given, but in the previous year. This dissociation probably would not have happened were the count a current one. It may be due to the fact that in the earlier source, as in the Oxkutzcab, the year bearers were placed opposite the Christian years in which the Maya year ended, and that the tuns, linked to the year bearers, suffered an even greater displacement. The omission in the Perez table of the tun 11 Zotz', which would have fallen in 1763, serves to restore the last 12 tuns

to their proper relation with the Perez year bearers: This was probably a deliberate correction, rather than a careless error, as Solis Alcala apparently believed it to be. It may be significant, too, that this correction is made at the point when the day series in the next to last column reaches the day 2 Ahau.

Both the Oxlutzcab and the Perez series of tuns contain other irregularities. In most cases, the month position given is that of Cauac, but sometimes it corresponds to Ahau, as, for example, 2 Yaxkin for 1537, 2 Xul for 1541 in the Oxlutzcab, and 2 Tzec for 1761, 2 Zotz' for 1764 in the Perez. The four occurrences of the same deviation at the beginning of the month suggest a pattern; but this pattern, if it is real, is largely obscured by other irregularities, some of which no doubt were errors of the copyist, as, for instance, the notation of 10 Uoo for 11 Uo in 1770.

Despite many errors and minor discrepancies, it is fairly clear that the tun series recorded in the Chronicle of Oxlutzcab was still understood and was being used in the middle of the eighteenth century; The long persistence of this particular count, whether it was continuous or not, should serve as strong confirmation of its authenticity, and should carry some weight in favor of correlations of Christian and Maya chronology, such as that of Thompson, which are based on its data.

If the compiler of the Perez table, however, was also the writer of the paragraph which follows, it is clear that he himself was not versed in the mechanics of the tun count, and that he did not understand fully the implications of the information he was imparting. In this paragraph, he gives explicit directions for finding the Ahau of the katun. The Solis translation gives the statement as follows: "El Ahau viene así: Cauac primer día de Pop, día del año nuevo. Al día siguiente empieza el Ahau Katun, cuyo día le da nombre. No hay que equivocarse, viene años tiene cada uno." This is followed by a somewhat equivocal explanation of the "nameless" days.

Throughout the codex, it appears that the native scribes, as well as Perez himself, accepted this statement as applicable to all katuns, which, according to their view, began on a day Ahau following the first day of Pop on Cauac years 24 years, apart. The original statement, however, could have been merely a specific instruction for finding the coming Ahau from the above table. In that case, the Cauac mentioned is obviously not one of the year bearer series, since here a Cauac occurs on 1 Pop every four years, and could not serve to indicate the katun. The reference is probably to the series of month positions in the last column. We are told that when Cauac in this column falls on the first of Pop, the next day will mark an Ahau katun. The fact that this Cauac is also

a year bearer is incidentally mentioned, but it is not necessarily relevant. As can be seen from the extension of the table, Cauac would fall on 1 Pop in 1776, and the next day, 2 Ahau 2 Pop is the katun date. Unfortunately the compiler did not continue his table far enough to discover this.

The statement seems to imply that katun 2 Ahau began rather than ended on this date. This is inconsistent with standard Maya practice. In Maya inscriptions, the katun day is almost invariably associated with the period preceding it, and it is generally believed that katuns were named for their final days. The naming of the katun by its initial date is strongly linked to the belief in the 24-year katun. One wonders, therefore, if the implication that 2 Ahau began at this time was part of the original information, or if there was a distortion of meaning caused by the paraphrase of an ignorant compiler. In any case, if 2 Ahau 2 Pop fell on the turn of a katun, its Long Count position must have been 12.8.0.0.0. This is in agreement with the Goodman-Martinez-Thompson correlation, as would be expected, since the latter is based on an identical tun series. In the Oxlutzcab version of the series, however, no katun is mentioned, whereas here it is expressly pointed out. A statement confirming the fact that a katun ended in 1776 is found on page 128. "El presente Ahau Katun lleva corridos 7 años y faltan trece para que termine. Su. año inicial paso en 1776" (Solis Alcala translation). Unfortunately the name of the katun is not given.

On page 126 the author states that he began his work in 1756 on the 10th of May, which was 19 Muan of a year 7 Cauac. This is not strictly accurate. Even if we accept the current practice of beginning the Maya year on July 16 (which probably was the primary cause of confusion about the calendar in colonial times), May 10 of 1756 would fall on 19 Muan of the previous Maya year, 6 Ix. If the year was 7 Cauac, then the author must have begun his writing in 1757. I am inclined to think this is more likely, for had he taken an interest in calendrical affairs before the autumn of 1756, he probably would not have missed the passing of 4 Ahau katun. The first tun he records, however, is 16 Tzec, which probably fell in September of 1757. Of the 4 Ahau 3 Xul which passed the previous fall, he apparently had no knowledge.

Possibly he accumulated his data for a number of years, for when he calculates the date of katun 8 Ahau on page 127, he states that it began in 1392, 384 years before the current date, which would then be 1776. His calculation is by 24-year katuns with 2 Ahau, 1776, as the primary datum. This probably is also the datum for the two katuns, 4 Ahau and 2 Ahau, recorded on pages 130–131. Twenty-one years

beginning with 1776 are listed for 2 Ahau, and the 20th is designated as its end. 4 Ahau, however, is projected back to 1752, when the Ahau coefficient corresponds to the day after the year bearer. 1771 is marked as the end of the katun, and the next four years are said to be “without name.”

It is tempting to think that this calculation was based on a misinterpretation of the specific instructions for finding 2 Ahau on page 125, and that it represents the invention of the 24-year katun on which later calculations were based. The tun series and the 24-year katun converge every 72 years, but the true katun and the 24-year katun could coincide only once in 1440 years, and if we accept the correlation which makes 2 Ahau the katun in 1776, it seems very unlikely that the Perez calculations should fall exactly at this convergence by mere chance. The possibility that the 24-year katun was already in existence, however, should not be overlooked. Roys (1949:92) cites in support of this view the series of katun prophecies that appear on pages 150–166 of the Perez Codex. These were copied in 1689 by Diego Chi, and accompanying them are lists of the 24 years which comprise each katun. Although these

lists and other references to the 24-year katun stand apart from the texts of the prophecies and could be separated as later additions, if they should prove to be contemporary another cogent possibility must be considered. If we project the Perez-Oxkutzcab series of tuns, the first tun of katun 9 Ahau would end on 7 Ahau 2 Pop in 1560. If this was chosen as the beginning of the 24-year katun 7 Ahau, then, 9 24-year katuns later, in 1776, 2 Ahau katun would begin on 2 Pop, just as the true katun was ending. The fact that the 24-year katun is said to begin on its Ahau date would satisfactorily account for ‘the choice of a first tun date, rather than the katun date as a base for the count.

Whatever the case may be, there is evidence that the 24-year katun did not supersede the older katun count, which seems to have persisted at least until 1796. Roys has recently called my attention to a table in the Kaua manuscript, which is similar to that in the Perez, and which covers the years from 1797 to 1824. The following is taken from a photographic copy in the library of the Peabody Museum of Harvard University (ch’ has been substituted for ch with crossed h in the original, and tz’ for the inverted c):

		Muluc Xaman	
1797	~~bolon~~ ti uuc Ahau	9 Muluc;	Cate Mac
1798	Ox Ahau	lahun oc	Uacлахun ti Ceeh
1799	Laca Ahau	buluc chuen;	bulucte; ti Sac
1800	Uaxac Ahua	lahca eb;	Uacte ti Yaax.
1801	Can Ahua	oxlahun ben	bulucte Ch'en
		Hyx Chikin	
1802	Oxlahun Ahau	hun Hix,	uacлахun; Mool
1803	bolon Ahau	ca men,	bulucte; tz'eyaxkin,
1804	hoô Ahau	ox Cyb,	uacte ti Xuul;
1805	Cabil Ahau	can caban,	caate ti Seec,
1806	buluc	Ho Etz'nab,	uacлахun ti (Zotz')
~~1807~~			
		Cauac Nohol	
1807	hun Ahau	uac Cauac	uacлахun ti Sip
1808	lahun Ahau	uuc Ahau	bulucte ti Uo
1809	Uac Ahua	Uaxac Ymix	uacte ti Poop
		1810	
1810	uuc Ahau	bolon Yk	caate ti Cunku;
1811	ox Ahau	lahun Akbal	bulucte ti Kayab;
~~1812~~			
		Kan lakin	
1812	Lahca Ahua,	buluc Kaan;	uacлахun Paax;
1813	uaxac Ahau,	lahca chicchan,	bulucte, Moan,
1814	Caan Ahua,	oxlahun Cymi,	uacte, Kankin,
1815	oxlahun Ahau,	hun Manyk,	bulucte, Maac,

1816	bolon Ahua	Caa lamat, Muluc ti xaman Cusut tucaten	caate, Ceeh,
1817	hoo Ahau,	ox Muluc,	cate, Saac,
1818	Cabil Ahau,	can ôc	bulucte, Yaax
1819	buluc Ahau	hoo chuen	uacte, Ch'en,
1820	hun Ahau	uac eb	uaclante, Mool;
1821	lahun Ahau	uuc been Hyx ti chikin	bulucte, tz'eyaxkin,
1822	uac Ahua	uaxac yix	bulucte ti Xul;
1823	oxlahun Ahau	bolon men	Cate, Sec
1824	uuc Ahau		
1825			
1826			

This table gives Christian years, a list of Ahau dates in partially regular tun sequence, a list of consecutive days as in the Perez, and finally a list of month positions. The latter are apparently intended as tun endings. Actually their distances are irregular and correspond roughly to a hotun series. The prevailing order of the coefficient series, however, seems to be similar to that in the Perez: 16, 11, 6, 2, 16, 11, etc. In spite of numerous exceptions, we note the descending order of numbers and, curiously enough, the use of 2 in place of 1 in the order. The month names are arranged in consecutive reverse order, changing every year, instead of every four years as in a proper tun series. Accepting this general scheme without regard to its meaning, we find that its starting point, that is, the notation that would normally precede 2 Mac in 1797, would be 6 Kankin in 1796. As we have seen, according to the Perez table, 1 Cauac 1 Pop was the day preceding the katun Ahau in 1776. One katun later, in 1796, this day would be 12 Cauac 6 Kankin, and the katun would be 13 Ahau 7 Kankin. This evidently was the datum used for the Kaua calculation, however erroneous it is in other respects. The first eight Ahaus of the Kaua table, beginning with 7 Ahau, are arranged in regular tun sequence. The next five notations are irregular, but the series correctly resumes with 7 Ahau in 1810 and repeats the pattern. The first notation of the Ahau in the original manuscript reads "bolon ti uuc Ahau." The "bolon" seems to have been crossed out and does not appear in the copy made by Gates about 1920. Since the first tun after katun 13 Ahau in 1796 is 9 Ahau, it appears that the compiler of the Kaua table used this datum, but made a change in the Ahau series. This is easily explained if we assume that he shared the common belief of his times that the day of its beginning named the katun. He may have had before him a statement to the effect that in 1796 the katun changed from 13

to 11 Ahau: "Bolon ti uuc Ahau" would be the corresponding Ahaus one tun later, and the compiler, believing that the f1 Ahau of the current katun fell at its beginning in 1796, continued his series of Ahaus from 7 Ahau rather than from 9 Ahau.

It is significant that the datum 13 Ahau 7 Kankin, 1796, could not have been calculated on the basis of the Perez manuscript, which assumes that katuns always began after a year bearer. Moreover, the compiler of the Kaua was obviously too ignorant of the mechanics of the tun count to calculate this datum himself from earlier information. This clearly points to a contemporary source of information uncorrupted by the prevalent ideas about the 24-year katun appearing in the manuscripts of the eighteenth and nineteenth centuries. Is it conceivable that as late as 1800, there were still Chilams who kept a record of the passing tuns by verbal tradition, or perhaps even in hieroglyphic writing? This question merits further investigation, for it now appears that the scribes of the books of Chilam Balam were not the best-informed sources of their time. Modern survivals of the Maya calendar, if they stem directly from verbal tradition, may be more closely related to the ancient count than are the notations appearing in nineteenth-century manuscripts, and the hope that colonial hieroglyphic records may yet be found is encouraged by the thought that the aboriginal katun count survived for at least two and a half centuries after the conquest.

This count, which is entirely consistent wherever series of tuns are given, agrees with the Goodman-Martinez-Thompson correlation. If we assume any of the other correlations proposed, we must also assume that the Maya calendar was changed before colonial times either deliberately or by error of the sole native authority which understood and preserved the ancient calendar system.

A Decorated Vessel Support from Acapulco, Mexico

Hasso von Winning

In recent years explorations in Mexico have yielded a type of vessel support previously unknown in prehispanic pottery. These supports are up to 20 cm high, plano-convex, and hollow. The flat exterior bears a stamped decoration. Although, as far as I know, no complete vase or dish has been recovered, it is generally assumed that they were tripods. Their occurrence has been noted at several points west of Acapulco (Ekholm 1948:99). The purpose of this paper is to supplement the few extant pieces with a rather elaborately decorated dish support purchased some 15 years ago at the Embarcadero in Acapulco (Fig. 113.1a, b).

It is 16 cm high and 6.5 cm wide, of brown, fine paste showing specular reflection. The front has a reddish brown slip and is lightly burnished, but the convex back remains unslipped. It therefore can be grouped in Ekholm's "Acapulco Brown" ware. There are two oval and one longitudinal vent holes in the back. The leg is hollow and does not contain pellets. Its original position on the vessel must have been slightly slanted so that the lower part projected outward. The bottom of the leg is smooth and shows almost no wear from usage. The leg belonged to a tripod dish with a 9 mm thick bottom, and flaring sides probably not more than 15 mm high. A reddish brown slip covers the interior surface of the dish. Very likely the supports were manufactured separately and attached to the dish before firing in a similar fashion to that followed in other areas where slab supports occur.

The relief decoration on the exterior was stamped; some details remain blurred. An attempt at description is based on an analysis of the component parts and their arrangement in comparison with stylistically similar motifs on classical Teotihuacan pottery. The person, in profile with a speech scroll, wears a feather headdress attached to a row of scrolls which are reminiscent of Teotihuacan-style wave crests. Below the scroll is a disc placed rather low as if intended for an ear ornament. However, the entire composition shows considerable disregard for proportions. Beneath his elbow the figure has a double disc, which is probably the *tezcacuitlapilli*, an ornament known from the codices, which, although worn on the back, is frequently shown frontwise on profile representations of priests. From his forearm and hand hangs a pouch, only half of which is shown to save room for a row of rectangular objects (probably grains of seed corn falling from the extended hand). Pouch and corn grains would characterize the image as a priest associated with fertility rites. The legs are over-simplified and ostensibly shown from the front. On the left side is an ornament resembling the *xicalcolihqui* (stepped fret) or possibly the symbol of a seat or temple turned 90 degrees to the right, to make it fit. The lower part shows a geometric design arranged in a rectangle, in similar fashion as the *cipactli* symbols on Toltec stone sculptures.

The arrangement of the different components, especially the face, bears marked resemblance to Teotihuacan style as represented on a molded design

113.1. Hollow slab supports: (a) from flat-bottomed tripod dish; Embarcadero, Acapulco, Earl Stehdahl Collection; (b) profile view of a; (c) molded design on exterior of jar (after A. M. Tozzer 1921a: pl. 16a).

of thin orange appliqué from Ahuizotla (Fig. 113.1c) illustrated by Tozzer (1921a, Pl. 16a). In both cases, isolated stylized motifs were assembled into a compact whole without using connecting lines or links. A fragment with an identical design, probably from the same mold, is in the Stehdahl collection.

Of the long slab legs found by Ekholm at Tambuco, near Acapulco, one specimen has a geometric design; another is too defaced for recognition, Weitlaner (1944; 1948) discovered at Coyuca de Benitez, some 25 km northwest of Acapulco, similar hollow slab supports with stylized animal heads. One shows a human head *en face* with the body in profile, in a style which he compares with the "Danzantes" of Monte Alban; another has a motif of drooping eyes. At the same locality he also found one small molded vessel support with Tlaloc symbols of typical Teotihuacan III type.

To date, surveys of the west coast of Mexico indicate that long hollow slab legs are characteristic of the Acapulco area. This leg form, together with several other traits in the same area, denote relations with the Teotihuacan culture complex, as pointed out by both Weitlaner and Ekholm. The latter cautions against dumping to the conclusion that the Teotihuacan site be regarded as the center of distribution.

LOS ANGELES

The Language of the Archaeologic Huastecs

Morris Swadesh

The Huastecs of the region of northern Vera Cruz have spoken a Maya language from earliest historic times. How long has this tongue been in the area? When and where in the ancient past did the forerunners of the modern Huastecs form part of a linguistic community with the other Maya? The problems raised by the linguistic connections are stated by Gordon F. Ekholm (1944:330):

“... Huastec is unique in being geographically isolated from all other members of the stock to which it belongs and which are distributed in a single block in Guatemala, Yucatan and adjacent regions. Between the Maya and the Huastec is a large area occupied by Totonac speaking peoples in central Vera Cruz and by peoples speaking various Nahuatl languages in southern Vera Cruz, Tabasco and Chiapas. This isolation of Huastec is usually considered to indicate that Maya-speaking people formerly extended up the eastern Gulf Coast from Central America and that a northern group was isolated at some remote time by the intrusion from the west of the now intervening languages... On the other hand, the linguistic affiliation is so close that it is assumed that the separation could not have taken place at a very remote time.”

Ekholm gives here a plausible culture-historical explanation which conforms with the archaeological evidence, but he has the impression that the linguistic evidence goes against his theory. Actually, the difficulty arises only from the vagueness which has sometimes characterized discussions of linguistic relationships. Huastec may be like lowland Maya

in some details and any such similarities would of course be striking in view of the great geographic separation, but they do not necessarily imply recency for the common period of Huastec and Yucatec. One may be struck by the close parallelism between contemporary Spanish and Russian verb endings (Spanish *ve-o, ve-s, ve-mos*; Russian *vyizh-u, vyidye-sh, vyidye-m* for “I see, thou seest, we see”), but both languages can be traced through centuries of recorded history, with gradually increasing similarities as one goes back in time, but with no period of identity and community within 22 centuries of Spanish and Roman history. Although it is not customary to speak of close relationship in such a case as Spanish-Russian, where much of the history is known, this sort of vague description based on partial similarities crops up more easily in the case of exotic languages. It is only thus that one can explain the supposed dilemma mentioned by Ekholm.

What is needed here is some relatively objective measure of linguistic divergence. This is provided by the method known as glottochronology or lexical statistics (see Swadesh 1952:452–453; Lees 1953). Since languages change with time and the changes accumulate in proportion to length of time, it follows that the splitting-up of a language community will be followed by diverging changes in the new communities proportional to the amount of time after separation. It has been found, in studies of historically known control cases, that noncultural vocabulary changes at a relatively steady rate which is not seriously altered by fluctuating cultural influences.

The index used in these calculations is 66 percent of common retention per 1000 years. That is, if a speech community becomes separated into two parts and the language therefore develops in two independent lines, eventually becoming two distinct languages, those two languages will still have about 66 percent of their basic vocabulary in common after 1000 years of separation. After a second 1000 years, the common vocabulary will be further reduced in similar proportion, so that it now amounts to 66 percent of 66 percent, or 44 percent. The mathematical formula is $t \text{ equals } \log C \text{ divided by } \log 66 \text{ percent}$; indicated divergence time in thousands of years is equal to the logarithm of cognate vocabulary percentage divided by the logarithm of 66 percent.

The cognate count is based on a standardized test list, consisting of 200 items of meaning, stated in English or any other convenient translation language. First, the most natural equivalent for each item is found in the two compared languages. Then the equivalent words are scored plus for cognate, minus for non-cognate, cognates being fudged by reference to the established comparative phonology of the two languages.

The third step is to obtain the percentage of cognates over total matched pairs. And, finally, the percentage is translated into divergence time by the use of the formula.

The method can be illustrated with a historically verifiable instance, that of English and German. Aligning the test vocabularies of the two languages, Lees (1953) found 58.5 percent cognates. This is somewhat less than the 66 percent which is retained after 1000 years and implies that the time of separation is somewhat longer than 1000 years. It works out to about 13 centuries of divergence (Lees, using a slightly different index and a formula for the 9/10 error, calculates it as 1236 plus or minus 246 years). This invasion and settlement of England by Teutonic peoples took place over the period between A.D. 450 and 600, and the latter date may be regarded as marking the full separation from continental Teutonic. Thus, the time of separation as calculated from common vocabulary retention proves to be very close to the actual historical time.

Applying this method to Huastec-Yucatec, we find 47 cognates in 178 matched pairs, or 26 percent, and calculate the time of separation at about 32 centuries ago. This is fully consistent with the theory of a very ancient continuous spread of Maya all along the coast, as suggested in the passage quoted from Ekholm.

The placement of Maya features in Huastec archaeology is given by Ekholm (1948:505):

“The speculation that the Huastec language is as old as Period II in the Huasteca best explains certain general characteristics of the archaeology of the area. Such a connection would have existed during the time of the Mamom and Chicanel phases of the Lowland Maya area when the culture there was relatively simple and the great period of the development of Maya culture had not yet begun. Dated monuments, polychrome pottery, and the use of the corbelled arch were yet to appear, accounting for the fact that none of these elements of ‘typical’ Maya culture are found in the Huasteca.”

Our lexicostatistic evidence thus confirms Ekholm’s conclusions and we can feel reasonably confident that the language of the archaeological Huastecs has been Maya at least as far back as Tampico-Panuco Period II. Details of the ancient language, in phonetics, in grammar and vocabulary, can be reconstructed by comparative linguistic methods to enrich the picture of ancient culture given by the archaeology.

The problem of Huastec-Maya separation as discussed in the foregoing is independent of the special connections which Franz Termer (1930) correctly points out between Huastec and Chicomuceltec. The latter is a close sister language of Huastec, related to it approximately as English is to German. It is therefore evident that the Chicomuceltec separated from the Huastec in relatively recent times, long after the Totonac moved in to separate the Huastec-Chicomuceltec from the main Maya area.

The linguistic disparity between Chicomuceltec and its immediate neighbors confirms its recent rejoining the main area.

The Huastec test list was kindly furnished by Norman A. McQuown, the Yucatec by Alfredo Barrera Vasquez. The scoring of cognates was checked by McQuown.

The 47 items scored as cognates, given in the order Huastec/Yucatec with diagonal-line separation, are:

ashes, tay’ / ta’an	louse, uts/uk
at, ti/ti’	many, yaan/ya’ab
bird, tsitsin/chiich	narrow, shuyat/shut
blood, shits/ kikel	one, huun/hun
bone, beklek/bak	road, beel/noh-be
burn, ta’iy/tab	scratch, lotsiy/la’ach
cold, tsamay/ke’el	seed, iilab/i’
come, taal/tal	sit, kwahat/kutal

day, kiichaah/kiin	skin, ot/ot
die, tsemets/kimil	deep, wayits/ wenel
dog, piko'/ peek	small, tsakam/chichan
drink, utsa'/uk	snake, tsan/kaan
ear, shutsun/shikin	stick, te'/che'
fire, kamal/ka'ak	sun, kiichaah/kiin
foot, akan/ok	there, tiwa'/te'lo'
four, tsee'/kan	thou, tataa'/tech
green, yashni'/ya'ash	three, oosh/osh
hand, kubak/ kab	tooth, kamab/ko
heavy, aal/aal	two, tsaab/ka'l
here, tehe'/te'la'	water, ha'/ha'
I, nanaa'/teen (common element-n)	white, thakni'/sak
kill, tsemtha'/kinsik	wind, ik/ik
laugh, te'en/che'eh	ye, shashaa'/te'esh
leg, akanlek/ok	

Items somewhat similar but considered probably not cognate are:

leaf, sheklek/le'	tongue, lekaab/aak
play, ubat/bashal	where, hu'tah/tu'ush
tie, wika'/kashik	

The words for father, taatah/taataa, may be due to relatively recent borrowing from a third language, perhaps Aztec or Mexican Spanish.

Items clearly non-cognate, indicated by giving only the English equivalent, are:

all	flower	name	star
and	fly	near	stone
animal	fog	neck	suck
back	fruit-berry	new	swell
bad	give	night	swim
bark	good	nose	tail
because	grass	not	that
belly	guts	old	they
bite	hair	other	thick
black	he	person	thin
child	head	pull	think
cloud	hear	rain	this
count	heart	right (hand)	throw
cut	hit	river	turn
dirty	hold	root	warm-hot
dry	how,	rope	wash
dust	hunt	rotten	we wet
ear	husband	rub	what
earth	if	salt	when
eat	in	sand	who
egg	know	say	wide
eye	lake	sea	wife
fall	left	see	wing
far	live	sharp	wipe
fat-grease,	liver	sing	with
feather	long	sky	woman
few	man	small	woods
fight	mear	smell	worm
fis	mother	smoke	year
five	mountain	some	yellow
flow	mouth	stand	

COLUMBIA UNIVERSITY
NEW YORK, N.Y.

A Stela at San Lorenzo, Southeastern Campeche

J. Eric S. Thompson

The small site of San Lorenzo lies 4 km north and slightly west of the chicle camp and water hole of the same name. These, in turn, are about 30 km in a direct line west by south of Aurora (Rio Bec) and about 8 km south by east of Hormiguero (Ruppert and Denison 1943, Fig. 1). It was visited by J. C. Harrington, Conrad Kratz (now Father Lawrence, O.S.B., and myself in 1936. The map was made by Harrington. The presence of a hieroglyphic stela in this region, where Peten and Rio Bec styles of architecture interlock, gives importance to the ruins.

The structures stand on an irregular, raised area, which follows the natural slope of the terrain and is bounded by a retaining wall of undressed stones laid dry. At its highest point this retaining wall stands 1.75 m, but removal of accumulated debris and fallen stones might increase this figure to 2.25 m or even 2.50 m. The general plan seems suggestive of Peten rather than Rio Bec usage, but the only standing superstructure is of Rio Bec type.

The whole of the front (west) of this one-room vaulted building has collapsed, but part of the lower zone at the back stands. This is faced with excellent veneer stonework of Rio Bec style. The stones are carefully dressed and fitted, and laid in rows averaging 19 cm high (an occasional stone is the height of two rows. In length the stones vary from 17 cm (exceptional) to 52 cm. They are turtle-backed. My only depth measurement is 23 cm, but that came from a stone of double height; to judge by similar masonry at nearby No Te Metas, stones of average size would be about 15 cm deep at the thickest point.

In contrast to the veneer masonry of the exterior, interior walls are faced with roughly dressed and irregularly quadrangular blocks averaging 20 cm high (17 cm and 27 cm are rare extremes) and 50 cm long (range 32–71 cm). Vault stones are around 9–13 cm high and 40–49 cm deep. Only part of the vault was standing. There was a cupboard (49 cm broad, 43 cm high, and 42 cm deep) in the east wall, 1.34 m below the spring of the vault.

The two buttress-like projections in the rear wall recall Rio Bec architecture, although nothing exactly comparable seems to be known. Together with the type of veneer masonry, it serves to classify the building as of Rio Bec style, in contrast to the plan of the site, which, as noted, is more suggestive of the Peten. It would appear, then, that both styles of architecture were used at this site either at the same time or one after the other. This problem, of course, has bearing on the cultural position of the stela, which is asymmetrically placed on the platform supporting the tallest pyramid at the site.

The stela stands to a height of 2.66 m above the platform, is 87 cm wide and 52 cm thick. Only the front is carved; this carries six large glyph blocks which retain considerable areas of red paint. The plain border has patches of blue paint. Some badly pitted areas are impregnated with paint in a manner suggesting that the stela might have been painted after it had been exposed for a long time to weathering. This is not certain, for the paint might have sunk deeply into the stone before it started to weather.

115.1. (a) Stela; (b) plan of San Lorenzo, made by J. C. Harrington.

Glyph 1 records 10 Ahau. The treatment of the features and the absence of a cartouche suggest late decadence (cf. paintings of Ahau on the Santa Rites murals). The absence of a month position strengthens the belief that this is a very late monument.

Glyph 2 is badly eroded. There is a u-bracket to the left. The remaining glyphs are illegible save the last, which is of unknown meaning.

A day Ahau without accompanying month position normally records the end of a katun since a katun was named for the day Ahau on which it ended. Furthermore, this small site, which apparently erected only one stela in its whole history, would almost certainly choose a katun ending for commemoration. In view of these factors and the apparent decadence of the glyphs, it is likely that this monument records the date 10.5.0.0.0 10 Ahau 8 Muan.

The features of the Ahau face and the absence of a cartouche around it make a reading of 9.12.0.0.0 10

Ahau 8 Yaxkin, the previous katun 10 Ahau, almost impossible (cf. records of this date on Stela 9 at Calakmul, and on Stela 6 at Uxul, illustrated in Ruppert and Denison 1943, Pls. 48, 58).

The late date proposed for the San Lorenzo stela finds some support in the late monuments at nearby La Muñeca, recording the dates 9.18.0.0.0, 9.19.0.0.0, 10.2.10.0.0, and 10.3.0.0.0. Recently, Proskouriakoff (1950:152) has suggested that a reading 10.3.10.0.0 for the date on Stela 5 at that site is worth serious consideration. This is only 30 years before the proposed date for the San Lorenzo stela. A jade bead from Tzibanche, to the east, is inscribed with the date 10.4.0.0.0.

In this remote area of southeastern Campeche and southern Quintana Roo the practice of erecting hieroglyphic stelae may have continued after it had ceased to the south. It must be emphasized, however, that the suggested reading for the San Lorenzo date is, at best, only a probability.

Ceremonial or Formal Archway, Uxmal

A. L. Smith and Karl Ruppert

During the latter part of April 1953, we spent several days, by invitation of Dr. Alberto Ruz Lhuillier, at the Mexican Government's archaeological headquarters at Uxmal for the purpose of investigating house mounds at the site and its environs.

While exploring south of the main group, we came upon the badly fallen remains of an unreported archway (Fig. 116.1) about 3 km south of the Governors Palace. It faces north and south and rests on a large platform. No evidence of a raised road or sacbe could be found associated with it. On the south side, 11.2 m from the base of the archway, four steps lead to the top of the platform. The masonry of the archway is of nicely cut stone laid in courses. At the level of the offset at the spring of the arch a single-member vertical molding, 22 cm wide and projecting 6 cm from the wall, extends around the outside. The walls were probably plastered and painted red as traces of red-painted plaster adhered to the under part of the molding and to the wall below.

Standing alone, unassociated with any other buildings; this structure appears to be a ceremo-

nial or formal archway, perhaps a triumphal arch. In possible function as well as in general appearance, it is very similar to the archway at Kabah. Stephens (1843:1:399–400) mentions this construction and shows a drawing of the archway at Kabah. Morley (1946:342, Pl. 56b) also mentions and illustrates it. The two arches are almost the same size: the one at Uxmal has a span of 3.3 m whereas the one at Kabah has a span of 4.1 m; however, the total breadth of the Uxmal structure is only 40 cm less than the one at Kabah. The length through the Kabah arch is 10 cm less than the former; the height from floor to capstone was probably about the same. Another archway of this type has been reported at Xculoc, a site 25 km south-southwest of Uxmal (E. M. Shook's 1940 field notes, and Carnegie Institution, Department of Archaeology, photographic files). This archway faces approximately north and south, measures 4.77 m through and has a total breadth of 8.01 m and a span of 3.89 m. Arches of this type standing alone are not common in the Maya area.

116.1. Ceremonial or formal archway, Uxmal: (a) looking northeast at archway; (b) looking northwest at archway; (c) plan and south elevation; (a) debris line; (b) ground level.

Miscellaneous Archaeological Specimens from Mesoamerica

A. V. Kidder

In the present Note are included various objects that do not form part of collections made in the course of Carnegie Institution's excavations, and therefore fail to find publication in reports on the Institution's field work. Although the exact provenience of few is known, all are of interest in one way or another. Some of the pottery vessels are of types hitherto unrecorded or ordinarily found only in fragmentary condition; some vessels and artifacts of stone and metal are of superior craftsmanship; others illustrate unusual or little-understood technological processes. Unless otherwise noted, all are from Guatemala and in the Museo Nacional de Antropología e Etnografía in Guatemala City. With certain exceptions, photographs were made under grants from the Colt Archaeological Foundation (1952) and the Wenner-Gren Foundation for Anthropological Research (1953).

Cylinder, tripod (Fig. 117.1). Dieseldorff Coll., M.N.A.E. no. 5433. Light gray paste. Interior and base unslipped, well smoothed; interior apparently smudged. Solid rounded feet. Exterior with low-gloss slip which has been brought to dark gray shade by the application of some liquid (see lighter gray band in central photo, an area not so treated; its right-hand edge shown in the drawing by a broken line). The slip has flaked extensively, exposing the previously smoothed surface, but from the areas between the upraised arms of the two bat (?) figures (stippled in drawings) it was purposely removed, throwing into very low plano-relief the large ears

and the ornament that rises from each head. The incising was done after slipping and polishing while the clay was in leather-hard condition. Ht. 21.5 cm.

The enormous collection that contains this and certain of the following specimens was made over many years by the late Erwin P. Dieseldorff of Coban, Alta Verapaz, who excavated extensively in that region, particularly at Chajcar and Chama, many of the finest pieces going to the Museum für Völkerkunde in Berlin. Certain of these and also a number retained in Guatemala that now form part of the Dieseldorff collection were illustrated in his *Kunst und Religion der Mayavölker* (1926, 1933), in which their provenience is recorded. Other objects from the above-mentioned diggings, together with the thousands purchased during his travels in the highlands and on the Pacific coast of Guatemala, were unfortunately never catalogued. In certain cases, to be mentioned below, it is possible to be reasonably certain as to place of origin; in others one can make a fairly good guess; in still others one is entirely at sea. The present vessel is in the guesswork class. It's straight, rather than gently concave, walls serve to differentiate it from the general run of Early Classic cylinders, which it resembles in possessing tripod support, although the Early Classic tripods usually have slab, not "nubbin," feet. In shape, its nearest analogues are straight-walled, "nubbin" footed vessels in the Rossbach Collection, now in the municipal museum at Chichicastenango (Lothrop 1936, Fig. 9 and Pl. 6). They were said by Padre Rossbach to be from Zacualpa, in the Dept.

117.1. Miscellaneous archaeological specimens from Mesoamerica.

of Quiche, not far to the west of Chama, but their period is uncertain. On the whole I would guess that the present Dieseldorff piece is of Alta Verapaz or eastern Quiche origin, both on the evidence of the specimens figured by Lothrop and because I think it likely that it was recovered by Dieseldorff himself, as he had done much excavating in that general region and, being a lover of fine pottery, would have saved and mended a vessel so badly smashed that few pothunters would have bothered with it.

I have indulged in this long discussion in order to illustrate the problems involved in locating important specimens in private collections, important because, as in the present instance, they are often complete examples of types either unknown or represented only by small fragments.

Cylinder with secondary decoration (Fig. 117.2a). Dieseldorff Coll., M.N.A.E. no. 5223. Matte interior, apparently smudged; well-smoothed flat base

a

b

117.2. Miscellaneous archaeological specimens from Mesoamerica.

slipped brown. Exterior bears creamy white slips very even medium-gloss finish. On this were painted bands vertically streaked with reds of varying intensity (all evidently applied with same brush) set 1 cm apart, leaving bands of that width reserved in the white slip. Secondary decoration probably completely obscured the primary, but has now so nearly disappeared as to re-expose it almost entirely. It seems to have been laid out with lightly painted hair-thin black guide-lines that served to place the small black inner diamonds. The larger black diamonds appear to have been drawn around the smaller. This may account for the irregularity of the pattern as a whole, its elements having seemingly been developed outward around the small diamonds instead of inward to fill a preliminary framework of crossed zigzags. The small diamonds, with central dots, were surrounded with white; on the black of the large diamonds were waved white lines. Both black and white were thin, unfired, and have lasted badly. Ht. 18 cm.

The bad condition of this unique vessel renders the method of its secondary decoration uncertain, i.e. whether the white elements were painted on a black ground, or were produced by some resist operation. Being a straight-sided cylinder without feet, it is probably Late Classic and, I would guess, from Alta Verapaz.

Cylinder with incised and resist decoration (Fig. 117.2b). Provenience unknown, M.N.A.E. no. 4646. Light orange paste. Matte interior apparently smudged, rim not blackened; flat base unslipped. Exterior slipped grayish cream. Very even, low-gloss finish, after which the incised lines were drawn with a sure hand after the vessel was nearly dry, for there is no burring and their edges are slightly abraded. The thin black pigment has nearly disappeared. Ht. 20.3 cm.

The combination of incising and resist and the frieze of serpent heads may ally this vessel to a bowl found by A. L. Smith at Nebaj, Dept. of El Quiché (Smith and Kidder 1951, Figs. 28; 74s). The latter, in turn, was thought perhaps to have come from Alta Verapaz (see Smith and Kidder 1951:66). It was accompanied in the Nebaj tomb by Early Classic vessels.

Tripod cylinders (Fig. 117.3a-e). Specimen a, private collection, Antigua, Dept. Sacatepequez, but provenience unknown; b, c, d Dieseldorff Coll., M.N.A.E. nos. 5230, 5702, 5703; e, purchased by E. M. Shook at Salcája, Dept. Quezaltenango. a. Feet open-bottomed. Reddish brown slip, rounded low-relief ornament on either side outlined with post-

finish scratch incising. Ht. 18.5 cm. b. Feet open-bottomed. Dark red, low-gloss slip from just within rim to and over basal molding, also covers outer surface of feet. Decoration of this and c, d, e, scratch-incised, post-finish and apparently post-drying; in each case repeated on opposite side; lines of c, d rubbed with white powder for photographing. Ht. 16.3 cm; c. Slightly "humped" feet, round 4 mm vents on each side of each foot, no rattles. Light brown to buff, low-gloss slip from just within rim to a band of thin, very light buff paint; medium gloss red slip from below latter band to edge of basal molding and over outer surface of feet. Ht. 15.3 cm. d. "Humped" mammiform feet, two round 4 mm vents on each side of each foot, no rattles. Dark red, medium-gloss slip from 4.5 cm down from rim on interior, covers most of exterior, including incised panels, to edge of basal molding and outer surface of feet; wall between panels is slipped orange (these areas with low, horizontal ribbing). Ht. 19 cm; e. Open-bottomed feet. Lowgloss orange slip, bands of thin light buff paint above basal molding, low boss on either side between decorations. Ht. probably about 19 cm.

These vessels are characterized by squat bodies, relatively large and often open-bottomed feet, low double moldings below rim, sharper basal molding, and post-finish scratch-incised decoration repeated on opposite side. Shook believes them to date from the early part of the Early Classic and to come from the vicinity of Salcája, a region in which great numbers of mortuary vessels have been dug by pothunters and sold to private collectors: Dieseldorff's collection also contains many pre-Classic pieces that surely came from the Salcája country. It is evident that he bought extensively there.

Tripod bowl, resist decoration (Fig. 117.5d), Dieseldorff Coll., M.N.A.E., no. 5155. Rounded rim; "humped" mammiform feet, each with a single round 6 mm vent on inner surface, no rattles. Interior and base evenly smoothed, matte, unslipped buff. From just within rim to lower edge of low moldings on exterior below orifice is well-polished deep red slip; a second band of same red, 1.5 cm, wide, encircles body above feet and carries down to cover their outer surfaces. Resist decoration, thrice repeated, in black on orange slip, between upper and lower red areas (see drawing). Ht. 13 cm.

Because of its low, rounded moldings at the rim and the slipping red of the upper exterior of its "humped" feet, I think there is little doubt that this vessel is from the Salcája region and contemporary with the tripods just described (Fig. 117.3a-e).

117.3. Miscellaneous archaeological specimens from Mesoamerica.

Effigy whistles (Fig. 117.6a-e), Kaminaljuyu. Dept., Guatemala. Mouthpiece with large opening through which air passes into almost spherical body, thence upward through a narrow cylindrical opening in a conical protuberance that extends down into the body, to strike against the sharp upper edge of a round 5 mm hole in the back of the hollow head, producing a high, piercing note. In drawing the section of d, the conical protuberance, not visible in the complete specimen, was reproduced from that of the detached head (see Fig. 117.6c, c'). All specimens of light brown paste with thin, matte buff wash. Traces of polished red decoration on b. As in most other pre-Classic whistles at Kaminaljuyu and elsewhere, birds are probably represented, although b and c are shown with earplugs; wings apparently indicated by appliqué lumps on both complete specimens. The two latter and some 20 heads were purchased; a was found in a late pre-Classic (Arenal phase) pit; c,

in a mixed deposit (Miraflores and Arenal phases). Ht. of d 6.3 cm.

Spouted tray (Fig. 117.5c). Found by resident at Copan Village, Copan, Honduras. Not from controlled excavation. White paste, red slip; three mammiform cascabel feet with single vents; length about 20 cm. Photo from G. Strömsvik. Specimen in municipal museum, Copan. A second, also from Copan, light brown, no feet, length 17 cm, is in Peabody Museum, Harvard.

Example of an uncommon but very widespread form, apparently confined to the pre-Classic. Records: *Mexico*. Gualupita, Morelos (Vaillant 1934, Fig. 23m), Gualupita II, mortuary piece, "granular" white ware, apparently no feet. Tlatilco, D. F. (Porter 1953, Fig. 13). Three from graves. White slip, no feet. Guatemala. Salinas de Istan, near Champerico, Dept. of Retalhuleu (Kidder 1940:10m). Weathered

red slip, head and legs of animal in applique, no feet, length 16.5 cm. Chimaltenango, Dept. of Chimaltenango, white ware, no feet. Alta Verapaz (locality?), Usulután decoration, no feet (two latter in Museum of the American Indian, Heye Foundation). Kaminaljuyu, Miraflores phase, two, Tomb I, Mound E-III-3, unslipped, no feet, length 10 cm. From same tomb one of chlorite schist, one of marble, both with three feet (Shook and Kidder 1952, Figs. 47a; 77e). I have record of only one fragment, Usulután, probably Miraflores phase, from among the hundreds of thousands of pre-Classic Kaminaljuyu sherds. This, and the fact that all specimens found under controlled conditions are from graves, suggests that this impractical-seeming form, it could not hold a liquid, was specially made for use in some mortuary rite.

Moldmade covers (?) (Fig. 117.3h). Collected by Kidder. Left, from Chontal ruin, Dept. Alta Verapaz; right, from Chuitinamit Atitlán, Dept. Solola, both late post-Classic, probably 14th or 15th century, sites. Very similar. Interior and exterior of rounded rim with polished red slip; rest of interior unslipped; unpolished brown; unslipped, decorated part of exterior worked over with smoothing tool that has softened edges of impressed design, most strongly on left specimen. Smooth bases slightly flattened; broken edges show them to have been perforated by round 3 mm holes, probably four to each. Diams., left 19, right 18 cm. Nature of relief decoration indicates that these bowl-like objects were made in molds similar to four illustrated by Ricketson (1935). They are of coarse, unpainted ware of the same size range and shape as these; his nos. 3 and 4 have running decoration much like that from Chuitinamit. The unfinished interiors of the present specimens and their perforated bases suggest that they may have been covers with string handles.

Red ware jar, dentate-stamp decoration (Fig. 117.5e). Collected by Shook at Finca Arabia, Dept. Quetzaltenango, at a Late Classic site, so identified by presence of San Juan Plumbate sherds. No material of earlier or later periods noted. Evenly surfaced, low-gloss, Dragon's Blood Red slip (Ridgway; Munsell reading 7.5R4-7) from interior base of neck, over rim, and to slightly below strap handles (mark on body of missing second handle). Pre-polish decoration done with seven-toothed implement whose marks measure 2.5 cm across curve. Ht. 40 cm. I know of no other case of similar decoration from Guatemala, nor any of rocker stamping.

Incised jars (Fig. 117.5a; detail photo shows part of largest sherd). Quirigua, Dept. Izabal. Coarse, unslipped, buff to grayish-buff ware with much white temper, some particles up to 1 mm. Outcurving rim, rounded edge, interior of rim flattish. This surface of largest sherd shows traces of red paint. Interior of all necks well smoothed; exteriors evened with tool that has left horizontal striations. Post-finish incising with three-pointed implement, two of the round-ended points being close together except in case of sherd at left center where the three were evenly spaced. Edges of lines slightly burred. Different tool used on each piece. Nature unknown but points evidently held firmly in position, as shown by even spacing of lines. Lip-to-lip diams. of jars 22–25 cm. Sherds collected (1934) by E. H. Morris and G. Stromsvik in excavating about butts of stelae in main plaza. Probably Late Classic. Unslipped, incised ware also occurs at the not distant and approximately contemporary sites of Copán (Longyear 1952, Fig. 30) and San Agustín Acasaguastlán (Smith and Kidder 1943, Fig. 39) but decoration is in multiple, parallel or criss-cross, usually individually drawn, lines.

Textured pottery (Fig. 117.5b). Quirigua. Coarse, unslipped, pinkish buff ware, 0.9–1.5 cm thick; from large jars or beaker-shaped vessels. Texturing of upper three seemingly done with bunch of stiff elements, perhaps grass-stems; a sherd from San Agustín Acasaguastlán apparently similarly treated (Smith and Kidder, 1943, Fig. 39c, second from left, top row); lines on lower Quirigua sherd individually drawn. Provenience same as foregoing incised sherds.

Thin Orange effigy vessel (Fig. 117.3f). Acalán, District of Tepeaca, Puebla, Mexico. Coll. Miguel Covarrubias. Ht. about 18 cm. Flat base, high-shouldered body, low rim and position of head are typical of this ware, but applique fillet arms and legs are so far unique, those members normally being naturalistically modeled (cf. Kidder, Jennings, and Shook 1946, Figs. 192–195).

Ornate incense burner (Fig. 117.4b). Thought to be from Chiptic, near San Carlos de Ococingo, Chiapas, Mexico; Hun Chabin is also said to have been its provenience. Specimen in Regional Museum, Tuxtla Gutiérrez, Chiapas. Mr. Giles G. Healey, to whom I owe the photograph, states that it is of brown ware with traces of fugitive blue paint. It is 92 cm high, and weighs some 80 lb. The fine preservation of this remarkable specimen makes it almost certain that it was found in a cave.

117.4. Miscellaneous archaeological specimens from Mesoamerica.

Cover of incense burner (Fig. 117.4c). Poptun, Dept. Peten. Light brown paste, matte surface; exterior is more carefully smoothed than interior. Remnant of cream-colored slip, or possibly stucco, on flat tap between forefeet of deer and on basal outcurve of wall; man and deer apparently unclipped; Traces of fugitive red on neckband of man. Antlers of deer and central element of man's headdress missing. Deer's body, neck, head, man's body, and head are hollow. Total ht. 26.5 cm.

The flat edge of the outcurving lower wall and the several vents in both deer and human figures indicate that this unique piece was the cover of an incense burner. Its excellent preservation suggests that it was found in a cave or a tomb. Period uncertain. Joyce (1933, Pl. VI, 12) illustrates a fragment of a moldmade figurine-whistle from Lubaantun, British Honduras, of a man with a spear about to plunge a knife into the neck of a crouching deer.

Flamed incense burner (Fig. 117.4a). Provenience uncertain, purchased in Antigua, Dept. Chimalten-

ango. Arrott Coll., photo by Mrs. Charles Arrott. Unslipped brown ware. Missing upper part probably flaring. Serpent heads appliqué. "Hourglass" type, i.e. with septum dividing annular base from receptacle proper, of which it forms the floor. In this case only base remains; septum at level of top of unusually short vertical side-flanges. Serpent heads appliqué, back plain. Ht. "as is" about 15 cm.

Stamp-decorated, hollow slab feet (Fig. 117.3g). Rio Coyolate, Dept. Escuintla. Coll. Raul Moreno. From probably shallow, doubtless tripod, bowls with dark red very highly polished floors. Feet unslipped, unpolished; single vent roughly cut through back wall with sharp-edged implement (obsidian flake-blade?) while clay soft; no rattles. Left: light brown; round 3 cm vent. Center: black; oval 2 by 1.3 cm vent. Right: round 2.5 cm vent; width across base 5.7 cm. Late Classic. Similar feet from San Jose, El Baul, and Tiquisate have been illustrated by Shook (1949, Figs. 9, 38) and Thompson (1948, Figs. 27, 46).

Tohil Plumbate toad effigy (Fig. 117.6f). Wild Cane Cay, British Honduras. Coll. Mr. Cabral, Wild Cane Cay. Front legs hollow, open at bottom; hind legs solid. Color orange with gray clouds. Ht. 14 cm. Cf. very similar effigy from Tecpan, Chimaltenango, Guatemala. (Shepard 1948, Fig. 14f): one of the only two other recorded vessels of plumbate from British Honduras is also from Wild Cane Cay, the head of a turkey effigy, Amer. Mus. Nat. Hist. (Shepard 1948:112).

The stone stamp shown in Figure 117.7e surely, the copper head in Figure 117.10c almost certainly, came from this little island off the south coast of British Honduras. Its several small mounds, of which only parts now remain, have produced a surprising number of unusual artifacts mostly, it would seem, from graves. Gann (1918:135) lists several copper objects and the carved femur of a deer. In 1950 Ekholm, Stromsvik, and I examined Mr. Cabral's present small collection. In addition to the Plumbate vessel there were shell beads, rings, pendants, an *Oliva* "tinkler," pottery ladle handles ending in human heads, and hollow moldmade animal-head feet from bowls (CIW. photo file nos. 50-1-23 to 31). The feet and ladle handles are of post-Classic types, Tohil Plumbate is post-Classic. We found no identifiably earlier sherds on the island.

Unit-stamp pottery decoration (Fig. 117.7). Sherds, a, b, f. from Poptun, Dept. El Peten; c Lubaantun, d. Mountain Cow district, British Honduras (c, d, in Belize Museum). From upper part of exterior of jars and large bowls with slightly constricted orifice (Fig. 117.7d, two upper). Three sorts of stamps were

b

a

c

d

e

117.5. Miscellaneous archaeological specimens from Mesoamerica.

117.6. Miscellaneous archaeological specimens from Mesoamerica.

117.7. Miscellaneous archaeological specimens from Mesoamerica.

used: a triangular-ended object to make lines of impressions along incised lines encircling the vessel (only on Poptun sherds); a dentate object with from three to seven points (Fig. 117.7c; only on sherds from British Honduras; see also Joyce 1925, Pl. XXVI, Fig. 2; and Mason 1928, Fig. 4); a stamp with a small round, square, or oval end bearing a carved device that was impressed in single or multiple horizontal lines. This was done after slipping and finishing but while the clay was still fairly soft. What is doubtless a stamp of this sort is in the Cabral Collection from Wild Cane Cay (Fig. 117.7e). It is of mottled brown stone, accurately shaped, round in section, square end with incised device. Length 9.4 cm.

The pottery from both Poptun and British Honduras is slipped red, reddish brown, or black (Fig. 117.7a); evenly smoothed, low-gloss. It is probably Late Classic or early post-Classic. Has not been found in north-central Peten (Uaxactun), on the Usumacinta (Piedras Negras), or in the Guatemala highlands.

Metates and mortar. Honduras. Coll. Melhado Bros., Trujillo. Tripod metate (Fig. 117.8a) of gray igneous rock and mano said to have been found with it on the Betulia Farm, 16 km west of Trujillo. Very evenly finished by pecking. Grinding surface shows slight lateral cupping by wear; mano considerably worn. Decoration of paired legs same, single leg undecorated. Length of grinding surface 77 cm, width at center 49 cm, length of mano 74 cm, greatest diam. 8.5 cm. Small tripod metate (Fig. 117.8c) believed to be from neighborhood of Trujillo. Gray igneous rock; upper surface slightly convex, no wear, presumably ceremonial object. Length, including head, 26 cm. Tripod mortar (Fig. 117.8e) vicinity of Trujillo? White marble, surfaces somewhat pitted, probably by earth acids. Total length 46 cm, ht. to rim of basin 22 cm.

Incised slab (Fig. 117.8d). British Honduras. From mound site near Santa Ana, 53 km from Belize on road to Corozal, Belize Museum. Nature of gray stone not noted. Greatest width 48 cm.

Stone carvings (Fig. 117.8b, g). Chutixtiox, Quiché. Late post-Classic. Specimens from tomb looted in prehistoric times, as unbroken floors pass over hole through which robbers entered (A. L. Smith 1955). Small human head, hard greenish white stone (note Jade); finely finished; perforated biconically above level of eyes; complete object, i.e. not broken from body; ht. 2.4 cm. Found in loose earth in tomb. Bearded figurine, soft grayish white, mottled stone; back flat; ht. 8 cm, thickness 2 cm. Animal carv-

ings; white stone, unpolished; carving same on both sides; thickness of both 1.7 cm; length of larger 8 cm. Found with the stone figurine in cut-down, flanged, hourglass incense burner that lay in tomb entrance. Also in entrance was a plain copper ring (Smith and Kidder 1951, Fig. 88f).

Stone face (Fig. 117.8f). Purchased in Mexico City, said to be from Valley of Mexico. Following data kindly supplied by Stanley Stubbs of the Laboratory of Anthropology, Santa Fe, where specimen bears no. 30-2620. Banded. light apple-green and gray serpentine; well polished all over; back slightly concave; traces of red pigment in pairs of biconically drilled a holes and at corner of right eye. Ht. 9.6 cm, thickness 3.8 cm.

Stone figurine (Fig. 117.9b), bearded man holding jaguar. Dieseldorff Coll., provenience unknown, presumably Guatemala. Dark green, apparently jade. Flexed left hind leg of jaguar appears under man's right forearm, tail paralleling right leg (central photo). Ht. ca. 18 cm.

Carved jade (Fig. 117.9a). Wax cast in University Museum, Philadelphia, no. 12518; gift of R. H. Lam-born, 1894. Provenience and whereabouts of original unknown. Was apparently in Boban Coll., no. 229 in sale catalogue, which reads: "Impression in wax of an antique Mexican cameo. See descriptive note by de Waldeck at back. 15 by 10 cm." The de Waldeck label now illegible. Information kindly supplied by J. A. Mason.

It has seemed worthwhile to make record of this specimen because it is so fine an example of an important class of carved jades of the late Classic period (for discussion of these jades see Smith and Kidder 1951:35).

Copper bells (Fig. 117.10a). Set found by native in casual digging in the Motagua Valley across the river from Quirigua, Dept. Izabal. Several are badly distorted by pressure from within (Fig. 117.10a) lower left and. lower right, and a'. S. K. Lothrop (1952, Fig. 8) illustrates the one figured here at lower left of a, turned to show the actual bursting-out of the wall. He believes (Lothrop 1952:25) that this was caused by steam generated in molds that had not sufficiently been dried. He also believes, I think rightly, that this is evidence of local manufacture, because such very defective pieces would hardly have become articles of trade. The bells are of Lothrop's Type B-3. Ht. of a, lower left, 5 cm; others to same scale.

117.10. Miscellaneous archaeological specimens from Mesoamerica.

Copper bell (Fig. 117.10b). One of six found in grave at Ixbobo, near Poptun, Dept. El Peten. Jaguar head seems to be represented, apparently in relief. I have not seen this or the other pieces in the set; present whereabouts unknown. Drawing, presumably natural size, shows it to belong to Lothrop's Type E. A bell of his Type B is in the National Archaeological Museum at Tegucigalpa, Honduras.

Copper heads (Fig. 117.10c, d). Specimen c is the best preserved of three very similar pieces in the collection of O.N.D. Phillips of Stann Creek, British Honduras, who is quite sure his late father acquired them at Wild Cane Cay. This hollow object still retains much of the tightly packed powdered

charcoal core over which the face was modeled in wax for casting *à cire perdue*. Drawing, natural size, by Mrs. Eugene C. Worman. Another almost identical copper head was found in a grave on Wild Cane Cay (Gann 1918:136, Fig. 83). Specimen d, formerly in collection of Hector Montano, present whereabouts unknown, was said to have been found on the island of Flores, Lake Peten, last stronghold of the Itza. Its close relationship to the foregoing is obvious. Natural-size drawing by Antonio Tejeda. Hollow copper death's-heads, like these in having no suspension rings, but unlike in that they have side-slits rather than open back crossed by bars, are illustrated by Lothrop from the Sacred Cenote (1952, Fig. 70).

Pottery Specimens from Guatemala I

Robert E. Smith

All save three (Fig. 118.4a-c, at present in the National Museum of Archaeology and Ethnology of Guatemala) of the 50 specimens herein illustrated came from the collection of General Frederico Ponce, who was at different times Jefe Politico of the Departments of Peten and Progreso. In 1944 Sr. Frederico Gonzalez acquired the collection, and that year I published an article (Smith 1944:39) in which were included five specimens reported to have been found on the north shore of Lake Peten Itza. These belonged to the Ponce collection; four of them (Smith 1944, Figs. 2g, h; 3a, b) undoubtedly came from the Department of Progreso, not from the Peten as I had been informed. They are typical of pottery from San Agustin Acasaguastlan (Smith and Kidder 1943). In the present lot, besides the three outside the Gonzalez collection, are a few that do not conform to our knowledge of Peten pottery; these (Fig. 118.1j, Antigua; 1, Progreso; Figs. 2e; ?; 3,k, ?) are given other possible sources or are questioned.

In spite of the lack of precise data as to the circumstances under which most of these specimens were discovered, the proveniences assigned them by their owners usually are correct. Furthermore, their cultural affinity generally is apparent. Among them are pieces that throw light on the technological processes or provide well-preserved examples of types hitherto known only in fragmentary condition. Consequently it is considered important to place these specimens on record.

Paintings and drawings are by Antonio Tejeda F. Scale of illustrations: Figs. 118.1 and 118.2, 1/4; Figs. 118.3 and 118.4, 1/3.

Fig. 118.1a-e. Unslipped gray to buff pedestal-based incense burners which resemble a Tepeu 3 type from Uaxactun (Smith, in preparation, Fig. 13m) more closely than they do similar examples from San Agustin Acasaguastlan (Smith and Kidder 1943, Fig. 22c-e, j). a. wall has appliqué spikes below which there is an encircling thumb-impressed fillet. While the clay was plastic, a circular hole was punched through the center of the floor; b. wall has a cluster of three appliqué spikes on at least two sides below which there is an encircling thumb-impressed fillet; and while the clay was plastic, circular holes were punched through the sides and the center of the floor; c. wall has appliqué spikes and a matlike ornament on one side (information lacking as to other sides), d. wall has an appliqué quatrefoil on one side (information lacking as to other sides). Circular holes were punched through center of floor and lower sides while the clay was plastic, e. wall has evidence of one spike (information lacking as to others), Circular holes were punched through center of floor and sides while the clay was plastic.

Fig. 118.1f. Jar, orange slip, low outcurving neck, globular body and a concave base. Atypical of the pottery of the Peten and Progreso save for slip color, which is more like that of the Peten.

Fig. 118.1g. Bowl, red-on-orange, flaring sides rounding to a flat base. Decoration consists of a broad red lip stripe on exterior.

118.1. Pottery specimens from Guatemala, I.

Fig. 118.1h. Probably a tripod dish, red on exterior and red orange-and-black-on-cream on interior. Decoration may be a broad glyph-like band on interior. This is a typical Tepeu 2 example (Smith, in preparation, Figs. 56o; 58b,7).

Fig. 118.1i. Probably the face of a Lacandon incense burner. It most closely resembles a type usually found to the south or east of Yaxchilan (Tozzer 1907, Pl. XVII; Fig. 2).

Fig. 118.1j. Rear view and profile of a hollow painted figurine (front view, Fig. 118.4d). There are vents in the side and base. This specimen, although from the original Ponce collection, probably came from nearer Guatemala City or Antigua, since it appears to be a Chinautla Polychrome type, as are two smaller specimens not of this collection (Fig. 118.4b, c).

Fig. 118.1k: Bowl (Fig. 118.2g) red-and-black-on-buff, outcurving sides which thicken considerably at base. Interior has broad red lip stripe on an orange slip; exterior has two panels with Serpent X and attached face (Ahau?) separated by parallel vertical stripes. The base has parallel stripes in contrasting red tones. This is a typical Tepeu 2, Uaxactun-style bowl. The Serpent X motif is usually associated with Tzakol and the Early Classic period, whereas the Ahau is a Late Classic feature.

Fig. 118.1l. Flask without neck, badly weathered. Has ornament on side and a ring base. Flasks are rare in Peten and therefore this specimen is more likely to have come from the Progreso region (Smith and Kidder, 1943, fig. 52).

Fig. 118.2a: Cylindrical vase, multicolor-on-cream. Interior has broad red lip stripe with a band

118.2. Pottery specimens from Guatemala, I.

of brown beanlike objects below. Exterior has a possibly functional glyph band and ceremonial scene with personage seated on throne conversing with two seated individuals facing him. An outstanding feature of this vase is a black background with decoration reserved in cream slip like that of the quetzal-decorated vase from Copan (Longyear 1952, Fig. 108a). Remarks: It is perhaps premature to say where this specimen originated. It has been suggested that the Progreso area is the most likely. I favor the Peten with the Alta Verapaz as second choice. There is the possibility, however, that these figure-painted vases were manufactured in only a few places specializing in this art and were widely traded throughout the lowland Maya area, western Alta Verapaz, and western Quiché. Uaxactun had a great variety of figure-painted cylindrical vases but none exactly like this. The Alta Verapaz, Quiché, and Motagua Valley vessels of this type each have a different style of interior decoration or slip. In this respect they all differ from Uaxactun, where various other interior decorative styles were encountered and among these one (Smith, in preparation, Fig. 2d) which has an almost identical interior border. Oddly enough, much of the exterior background of the Uaxactun vase is black with clusters of discs reserved in the cream slip.

Fig. 118.2b. Pottery drum. Orange polished slip all over exterior but thinner and less polished near larger orifice end. Interior unclipped. Exterior has horizontal red stripes framed by black lines. Vessel shows no wear. Late Classic, Tepeu 1, type a. Data on the distribution of drums will be contained in R. E. Smith's monograph in preparation on the pottery of Uaxactun.

Fig. 118.2c. Bowl with rounded sides. Orange polished slip all over. Interior has red lip stripe. Exterior has a black rim stripe with horizontal black line below, and a red and black central motif consisting of the "twist and bud" design also found in a cave at Pusilha on vessels of similar form (Joyce, 1929, Pl. XLIII, b, h). Late Classic, Tepeu 1 type.

Fig. 118.2d. Jar with outcurving neck. Orange polished slip. Interior has a broad lip band. Exterior has a red and black glyph band encircling the neck framed by red and black lines. Late Classic Peten type.

Fig. 118.2e. Jar with high neck, globular body and ring stand base. Buff polished slip on exterior. Horizontal red stripes and lines and a band of dotted arcs

on shoulder are all that remain of the decoration. The ring-stand base and high neck suggest a plumbate form. No good comparative material available.

Fig. 118.2f. Bowl, red-and-black-on-cream, with outcurving sides which thicken considerably as they approach the concave base. Interior has orange slip with broad red lip stripe and vertical stripes below. Exterior has a central band of S-shaped figures and dot-outlined ovoids framed with black lines and stripes. The base is bordered by a black stripe and encircled by a red stripe joined by a series of vertical red stripes (Smith, in preparation, Fig. 2m). Late Classic, excellent Tepeu 2 type.

Fig. 118.2g. See figure 118.1k for profile and extended design.

Fig. 118.2h. Bowl, red-and-black-on-cream, with outcurving sides which thicken considerably as they approach the concave base. Interior has orange slip with broad red lip stripe. Exterior wall has a broad band of alternating forms of the kin glyph reserved in the cream slip and framed by black lines. Base has parallel stripes in contrasting red tones. Late Classic, excellent Tepeu 2 type.

Fig. 118.2i. Bowl, red-and-black-on-orange, with flaring sides. Interior has black lip followed by a broad red band. Exterior wall has broad band of alternating red and black bracket designs, and base has parallel stripes in contrasting red tones. Late Classic, excellent Tepeu 2 type.

Fig. 118.2j. Same as Figure 118.2f in form save for size and design except for minor details.

Fig. 118.3a-h: Unslipped and weathered mold-made human figurines, often whistles, Late Classic. A. whistle figurine of fat man wearing what may be quilted apparel. This type was found in Guatemala at Uaxactun (Smith 1936, Fig. 17, no. 5), Chisec (Dieseldorff 1926, Fig. 48), Temal near Chama (Dieseldorff 1926, Fig. 49), in British Honduras at Lubaantun (Joyce 1933, Pl. VIII, 19), and in Mexico at Cintla, Tabasco (Seler 1915:150, Fig. 17, upper center); at Oxkintok, Yucatan, a similar figure occurs sculptured on a stone doorway column (Shook 1940, Fig. 7). b. whistle figurine of seated woman wearing wide-brimmed conical hat, a type often encountered in the Peten at Uaxactun (Smith 1936, Fig. 17, no. 4) or Poptun (Smith 1950:13) and more rarely elsewhere at such sites as Copan, Honduras (Longyear 1952, Fig. 87h), and in the Comitán Valley of Chiapas, Mexico

118.3. Pottery specimens from Guatemala, I.

(Blom and La Farge 1926–1927, Fig. 348c); c. figurine, probably whistle, of woman with Classic features, stepped hairdo, and blouselike garment reminiscent

of a figurine from the Dieseldorff collection considered to be of Coban style (Smith 1952, Fig. 23b), d–h are all possible Peten types.

118.4. Pottery specimens from Guatemala, I.

Fig. 118.3i. Probably figurine headdress similar to one from Uaxactun (Smith 1936, Fig. 16, no. 16). Late Classic.

Fig. 118.3j. Solid jaguar head which might be part of headdress (Smith 1936, Fig. 16, no. 14) or the head of a jaguar figurine. Late Classic.

Fig. 118.3k. Small modeled animal figurine.

Fig. 118.3l. Moldmade monkey and young, possibly a figurine whistle. Late Classic.

Fig. 118.3m. Modeled bird whistle figurine, similar to one from Uaxactun (Smith 1936, Fig. 17, no. 8). Late Classic.

Fig. 118.3n. Moldmade grotesque, a whistle figurine. Late Classic.

Fig. 118.3o. Modeled monkey figurine.

Fig. 118.3p. Modeled doglike figure seated on a possible flageolet. Late Classic, Flageolets were found at Uaxactun (Smith 1936, Fig. 16, nos. 13, 18; Fig. 17, no. 14).

Fig. 118.3q. Modeled grotesque head attached to an ocarina. Probably Late Classic.

Fig. 118.4a. Cylindrical vase, black-on-gray, incised monkey panels separated by rectilinear guilloche panels. This vase was reported to have been found at Flores, Peten. It is similar to a Tepeu 3 specimen (Smith, in preparation, Fig. 43a, 6).

Fig. 118.4b. Hollow figurine, probably Chinautla Polychrome. Acquired in Antigua, Guatemala. Late post-Classic.

Fig. 118.4c. Hollow figurine, probably Chinautla Polychrome. Belonged to Sr. Luis Martinet of Guatemala City. Late post-Classic.

Fig. 118.4d. Hollow figurine, probably Chinautla Polychrome. Late post-Classic. For further information see Figure 118.1,1.

Fig. 118.4e. Tripod (?) plate, red-and-black-on-cream. Interior wall has red rim stripe and basal stripe outlined with black lines which frame a black glyph band. Exterior, vertical stripes in contrasting red tones, Typical Tepeu 2 style (Smith, in preparation, Fig. 56m-p).

Fig. 118.4f. Tripod (?) plate, red-and-black-on-orange, but otherwise very like e.

Fig. 118.4g. Fragment of plate floor, orange-and-black-on-cream showing. Design appears to be stars outlined with black, Tepeu 2 motif (Smith, in preparation, Fig. 39x,7).

Fig. 118.4h. Effigy bowl. The face and loop between the eyes is reminiscent of like features associated with vessels from Uaxactun in the Peten (Smith, in preparation, Fig. 75b,3), Rocnima and Panzamala in the Alta Verapaz (Dieseldorff 1926, Figs. 175 and 176 respectively). Late Classic (?).

Fig. 118.4i: Flageolet (?) with effigy human head at one end. Late Classic.

Fig. 118.4j. Cylindrical stamp. Possible roller stamps were found at Uaxactun in Mamom refuse (Kidder 1947, Fig. 59c; Ricketson and Ricketson 1937, Fig. 145e, f).

Fig. 118.4k. Small jaguar-face mask (?) No trait suggestions as to its provenience or cultural period.

Drawings of Glyphs of Structure XVIII, Palenque

Miguel Angel Fernandez

WITH NOTES BY HEINRICH BERLIN

During his ten years' work at Palenque from 1935 to 1945, the late Miguel Angel Fernandez, artist rather than notebook-filling archaeologist, used his pencil primarily for drawing new finds. Through the courtesy of his heirs it is possible to present his drawings of the glyphs of Structure XVIII at Palenque; photostats of a few drawings of material from other parts of Palenque are on file at Carnegie Institution's Department of Archaeology, but many are still missing. The publication of those of Structure XVIII will furnish the student of glyphs with fresh material and at the same time fix permanently the exact location where they were found.

These 54 stucco glyphs (Fig. 119.1-3) were found in the debris by me in 192 (Berlin 1944). They measure 13 by 14 cm. To establish their positions, the glyphs in Blom's drawing (Blom and La Farge 1926(1), Fig. 135) were labeled, from left to right, A, B, and so on. Thus each glyph is named first with a letter referring to the one of Blom's series under which it was found. Glyphs found farther to the left of A were named A/. Of the two numbers which follow, the first measures in centimeters the vertical height from the glyph to the inset step of the vault; the second measures the distance from the rear wall to which the glyphs originally adhered.

I studied the numerical part of Glyphs 33, 37, and 49, and suggested in Note 33 of this series that it was

a head variant of number 11. Later, J. E. S. Thompson (1950:135) established as distinctive of number 11 the presence of the Caban glyph. Now, the drawing of Glyph 37 shows the rings (which I thought to be the distinctive features) and, on the cheek, the Caban sign, not shown on my previous illustration (1944, Fig. 1c), which was drawn from a poor photograph. Hence the tentative identification made ten years ago is now definite for this particular case. I am, therefore, of the opinion that despite the absence of the Caban sign in the three other cases discussed in my earlier paper, they still may stand for number 11.

Of the glyphs in Structure XVIII found *in situ* by Blom, only sketches have been published. Most of these are now in the storeroom at Palenque, and were photographed, together with those found in 1942 and here illustrated, by J. Eric S. Thompson. As details of some of Blom's drawings are not too clear and fail to illustrate the beauty of their delineation, I include photographs of those that survive (Fig. 119.3, nos. 55-73). For identification purposes those grouped below the main band are given the corresponding letters in italics with numbers corresponding to the vertical position. Those illustrated are: B, C, D (part), E (part), F, I (part), K, L, M (part), A, B, D, E1, F1, G1, G3, H1, 12, L2 (reversed in Blom's drawing). It will be noticed that several have been damaged since Blom drew them.

119.1. Glyphs of Structure XVIII, Palenque.

Memoranda on Some Dates at Palenque

J. Eric S. Thompson

In a discussion of lunar systems at Palenque, Heinrich Berlin (1943) argued that Palenque had adopted the uniform system of reckoning moons. The evidence was not entirely satisfactory because of the two dates which he used to support his idea: one (Templo Olvidado) fell outside the period of uniformity with an IS 9.10.14.5.10 3 Oc 3 Pop (Berlin 1944), and the other was incomplete.

This incomplete record was a fragmentary text found in 1942 by Miguel Angel Fernandez in clearing the substructure of the Temple of the Sun. Berlin suggested that it be restored as 9.12.19.14.12 5 Eb 5 Kayab. In that case, as he pointed out, the lunar date (3C 11D) would conform to the uniform system. Unfortunately, there was the doubt as to whether the 5 ? Kayab which alone survived of the date could be amplified to 9.12.19.14.12 5 Eb 5 Kayab.

In the course of a visit to Palenque, as guest of Senor Alberto Ruz and the Instituto Nacional de Antropologia e Historia, in July 1951, I noticed in the archaeological storeroom a fragment of stone with eight glyph blocks on it (Fig. 120.11), and this fitted to the piece already described and illustrated by Berlin.

The first fragment ends with Glyph X4 of the lunar series. The new piece commences with Glyph B, next in sequence in the lunar series, and this is followed by Glyph A9.

A distance number of 1.7.11 leads to 1 Imix 19 Ch'en, the juxtaposed glyphs indicating in abbreviated form that this is a basal position in the 819-day cycle. The only position in Baktun 9 which this CR

can hold as a basal position in that cycle is 9.12.18.7.1. Accordingly, the text can be restored:

9.12.19.14.12	5 Eb 5 Kayab (moon age 3C, 11D, A9)
1.7.11	Subtract
9.12.18.7.1	1 Imix 19 Ch'en

The discovery of this fragment fully authenticates Berlin's reading, and shows that he was right in his supposition that there was a period of uniformity at Palenque. Actually, his opinion has been since proved by the discovery of records in the uniform system on the tablet recently discovered by Ruz (Thompson 1952).

As in other cases, there is a count backward of less than two tuns to reach the basal date. Only three interpretative glyphs are recorded.

I believe that it is possible that the same IS, but this time with a lunar series perhaps not in conformity with the uniform system, may have once been recorded on the two outer pilasters of the Temple of the Sun.

Among the drawings of Miguel Angel Fernandez in the possession of his heirs (see Fernandez and Berlin 1954) are several of stucco glyphs recovered from the debris at the foot of the north and south pilasters (Fig. 120.1, nos. 2-13), and in that connection I am indebted to Berlin for reminding me that Waldeck's drawing of the front of the temple (Brasseur de Bourbourg 1860, Pl. 26) shows four of the glyphs of the IS *in situ*.

The Waldeck drawing illustrates two medallions one above the other, each containing four glyph blocks, but Catherwood's drawing and Maudslay's photograph make it clear that there were six glyph blocks in the lower medallion. Waldeck shows an IS introductory glyph (A1-B2) with a youthful face as the variable element, a clear baktun sign with a coefficient which is probably meant to be 9 (A3), and a katun sign with a coefficient which is 12, 13, or 14 (B3).

The only glyph in the lower medallion is the tun sign occupying the first glyph block (A4). Waldeck drew it with three bars to the left and then crescent, dot, crescent, dot. Such an arrangement would be most irregular. Luckily, we have Fernandez' drawing of this glyph (Fig. 120.1, no. 2). The numerals had clearly suffered in the century between these two drawings. He restores Waldeck's second crescent as a dot and his second dot as a crescent. However, from what original remains in Fernandez' drawing, both his crescents are open to question, and a combination of Waldeck's and his drawing would fit either 17 or 19.

Fernandez also recovered from the south pilaster debris the following glyphs and fragments: two damaged coefficients restorable as 12 and 14 respectively, and part of a glyph which might be G3 (Fig. 120.1, nos. 3–5).

From the debris at the foot of the north pilaster Fernandez recovered Glyphs X4, B, and A10 of the lunar series, an Imix, a tun sign, a Muluc compound, a coefficient restored as 11, and part of a head, conceivably that for number 5 (Fig. 120.1, nos. 6–13).

Fernandez' glyphs are either to scale or half scale, and are so marked. It is clear that the glyph block was 22 cm high and 22–24 cm wide, and that Glyphs X4, B, and A10 occupied half a glyph block each.

The present heights of the Imix and tun signs (16 cm and 15.5 cm respectively) show that neither is complete. Fernandez tentatively attached the coefficient of 11 to Imix, but that requires restoring the pedestal of Imix as 6 cm high. I believe that the Imix was not a day sign at all, but formed part of an Imix compound, perhaps the Imix comb–Imix sign. Similarly there is room to place a large coefficient to the left of the tun sign and the katun element above.

A serious difficulty is that, according to Fernandez, the detached coefficient of 14 from the south pilaster has a height of only 15 cm. As there is room on the south pilaster for only three glyphs or glyph blocks in addition to the IS, and those were probably the day sign, month sign (?), and Glyph G3, it is hard to see how this coefficient can be anything except a period or month sign coefficient. Unless it fell from the adjacent pilaster, which had an inverted L of glyphs, Fernandez must have made an error in the scale.

The youthful head in the IS introductory glyph strongly favors a position in the month Kayab, although Zec and Mac are weak possibilities. To derive the IS from what we have can not be more than a guess, but I would suggest the reading: 9.12.19.14.12 5 Eb 5 Kayab G3 11D, 3 or 4 C, X4, B, A10. The parts [italicized] have some support in Waldeck's or Fernandez' drawings. The IS, as we have seen, occurs on a stone tablet from the substructure of the Temple of the Sun, and appears as a CR on the Death Head monument; on Blom's Tablet 1, discovered at the back of the Pyramid of the Sun; on Blom's Tablet 2, found on the west side of the Pyramid of the Foliated Cross and correctly assigned to its present position by Berlin (1945), and by the stairway of the Temple of the Cross. The fact that this date is a slogan, to use Teeple's vivid term, at Palenque makes it more probable that the IS has been correctly interpreted.

Accepting the date as correctly read, let us compare its lunar series with that on the stone text from the substructure:

Stucco text, Pilasters of Temple of Sun	G3, 11D, 3 or 4C, X4, B, A10
Stone text, substructure of Temple of Sun	G3, 11D, 3c, X4, B, A9

As Glyph A usually has a coefficient of 10 when Glyph C has an odd-number coefficient (approximately 8 to 1 chance during the period of uniformity; slightly less than 3 to 1 chance outside that period), it is probable that in the stucco text the missing Glyph C had a coefficient of 3.

Apparently, then, we have two lunar series for the same date which differ only in that one, which conforms to the moon numbering of the period of uniformity, has A9 instead of A10 which one would normally expect. The other (the stucco text) has the more usual A10, but because of the disappearance of Glyph C, we do not know for certain that its coefficient was 3, although it must be 3 or 4, and inherent probability calls for 3C.

If the stucco inscription is correctly read, these two texts may record the adoption of the uniform system at Palenque. Copan recorded the adoption of the new system with the IS 9.12.8.3.9; Piedras Negras and Naranjo chose respectively 9.12.2,0.16 and 9.12.10.5.12, and both cities recorded their starting date twice, once in the uniform system and once in the system each previously used. Palenque, if our decipherment is correct, chose 9.12.19.14.12. All four fall in Katun 13 (the double date at Yaxchilan seems too late to record the introduction of the uniform system there). As each city seems to have had its

own system of grouping moons prior to the period of uniformity, the nature of the change involved in a shift to the uniform system varied. At Piedras Negras the coefficient of Glyph C and the age of the moon both decreased by one and the coefficient of Glyph A dropped from 10 to 9. At Naranjo the coefficient of Glyph C increased by one and the moon age decreased by a day, and there was a rise of Glyph A from 9 to 10. At Palenque, if our ideas are correct, the change was accompanied only by a substitution of A10 by A9 (or vice versa), and conceivably by a change from C4 to C3. Unfortunately, because of the uncertainty surrounding the defective stucco text, it is not possible to place much reliance on this as an example of double-dating to usher in the uniform system. If the missing Glyph C on the stucco inscription recorded C3, as is probable in view of the record of A10, both the independent system at Palenque and the uniform system happened to agree at that particular date on the number of moons. Such an agreement does not occur in other double dates, but there is nothing to rule out chance agreement between the two systems. In that case, it is not possible to say which of the two combinations, C3 and A9 or C3 and A10, represents the uniform system.

A matter of some interest is that if the fragmentary glyph is correctly identified as G3, the same mistake of recording G3 instead of G4 occurs in both texts. The fragmentary tun sign is perhaps restorable as 13 katuns.

One small glyph, a tun sign or perhaps an irregular version of Beyer's serpent segment, was also found in the debris near the south pilaster. As it is only 9 cm high and 9 cm wide, I suppose it fell from the adjacent pilaster. This and detached glyphs from the central pilasters are illustrated (Fig. 120.1, nos. 14–21).

The defective stucco inscription on Pier A of House A of the Palace has attracted the attention of both Beyer (1936) and Berlin (1945). The identification of the head numeral for 11, made since these decipherments were published, throws fresh light on the subject, for the head attached to the katun sign of the IS is clearly that of the number 11. The decipherments offered in the two papers must, accordingly, be rejected.

Berlin noted the faint outline of the hooked nose and tun headdress of the god of number 5 in the head attached to the kin sign, but he believed that a jawbone, converting the head to that of 15, was not present. I, on the contrary, felt strongly that that element was discernible in Maudslay's published photo. After the decipherment, given below, had been made, Berlin, with whom I had discussed the matter, re-examined the head in the course of a

recent visit to Palenque. He informs me that he is now convinced that the jawbone is present. We have, then, the following:

9.11.?.?.15	? Men 8 Zec
-------------	-------------

There is a further check. Glyph D of the lunar series (here the up-ended frog found elsewhere at Palenque in replacement of the normal forms of Glyph D) appears without a coefficient. Accordingly the moon age must be from 20 to 29 days, or, possibly, 0 days.

There are only two dates in Katun 11 with Men on 8 Zec with moon age between 20 and 29 days or at Maya new moon:

9.11.6.12.15	9 Men 8 Zec, moon age 23.8–26.3
3.9	
9.11.6.9.6	5 Cimi 19 Pop

and

9.11.14.14.15	4 Men 8 Zec, moon age 20.3–22.8
3.9	
9.11.14.11.6	13 Cimi 19 Pop

The higher figures for moon age are calculated from the table compiled by Lawrence Roys (1945); the lower figures are computed from the moon age of 19 days given at Palenque for the IS 9.12.6.5.8.

The little that remains of Glyph Block A5 might indicate G3F, in which case the first reading must be correct. However, the identification is far from reliable. It may or may not be significant that 9.11.6.9.6 corresponds to March 19, A.D. 658 in the 584283 correlation.

The dates following the IS of the hieroglyphic stairway of the Palace are somewhat eroded. The most acceptable reconstruction would appear to be:

A1-A4	9.8.9.13.0	8 Ahau 13 Pop
B5	12.9.8	
	9.9.2.4.8	5 Lamat 1 Mol
A6	2.12.3.3	Add to IS
A6-C1	9.11.1.16.3	6 Akbal 1 Yax
C4	9.11.6.16.11	7 Chuen 4 Ch'en

The reading of the IS and of the 5 Lamat 1 Mol date has been generally accepted for many years. Date 3 appears to follow the practice common in other parts of Chiapas of counting from the IS, not from the date last reached.

Snares and Traps in Codex Madrid

Jose Luis Franco

Codex Madrid contains several divinatory almanacs (pp. 42c, 44–49, 90a–92a2, 92a3–93a2), with illustrations of animals in traps. Of the 76 animals pictured, 20 are deer, two are peccaries, two are turkeys, and two are armadillos. I follow the usual identification of the animals, a topic extensively discussed and, I believe, settled by now. The matter of traps, though, has hardly been considered, the only detailed discussion, to my knowledge, being that by Cyrus Thomas (1882:97). Thomas correctly identified the snares (Fig. 121.1, nos. 1–4), but only suggests the necessity of some kind of triggering device. Contradicting Brasseur de Bourbourg, he thinks the trigger might be the curved element in the lower part of 121.1, no. 3. He explains 121.1, no. 10 as a pitfall “lined around the sides with upright pieces of wood.” We shall see that this is not correct.

In the belief that such knowledge could perhaps be helpful in the interpretation of some glyphic matters, I have had a special interest in the functioning of these traps, but the high conventionalization of the drawings in the codex was a very great obstacle to successful analysis.

Some years ago I was fortunate enough to meet Juan de Dios Rosales, who was then completing a very exhaustive ethnological investigation of his native region in the Tzutujil country of Guatemala. This study, “La cultura material de un pueblo Tzutujil: San Pedro de la Laguna,” will be published by the government of Guatemala.

Rosales asked me to draw the illustrations for his book. On accepting, I found that his “trampas,

instrumentos de caza y pesca, recoleccion y armas” contained the data for which I had been searching, although subsequently I discovered similar material in Blom and La Farge (1926–1927:352), Wisdom (1940:74–77), and Thompson (1930:87).

There is nothing very special about the traps under discussion, they are very common ones, but in order to reduce to a minimum the imaginative factor of the analysis I needed what I now have: a precise, comparable, and well-illustrated documentation containing material analogous to the codex, and coming from an ethnic group known to be more or less directly related to the makers of the manuscript.

There are four types of traps in Codex Madrid: snares (using as a motor agent a sapling), deadfall traps, pitfalls, and nets.

Snares. Most of the snares in the codex have caught a deer (Fig. 121.1, nos. 1, 3). In two instances the captured animal is a peccary (Fig. 121.1, no. 2 and Madrid 93a1) and in the remaining one a turkey (Fig. 121.1, no. 4). These traps, as well as all others, picture only the most indispensable elements sufficient for their ready identification by people who knew them in their daily experience. Another factor contributing to the oversimplification is the very small space allotted to the illustrations in several of the almanacs. For this reason, the smallest and most complicated component, the trigger mechanism, had to be eliminated.

Among the Tzutujils, Rosales found in use the snare illustrated in Fig. 121.1, no. 8. As in the case of

121.1. Snares and traps: (1–6) snares; Madrid 45b, 49a, 49b, 91a3, 44a, 49c; (7) the god of hunting supports the sapling on his head; Madrid 45c; (8) snare used by present-day Tzutujil; (9) Deadfall trap used by present-day Tzutujil; (10, 11) deadfall traps; Madrid 48a, 91a1; (12) pitfall trap; Madrid 92a1; (13) net trap; Madrid 93a2.

Fig. 121.1, no. 4, this was for catching fowl. We may then, at least for this particular case, safely infer that the ancient Maya traps worked similarly.

Fig. 121.1, no. 8a, is a little flat stone, in the direction of which the bird is lured by a row of corn grains. The trigger proper is a short stick c, maintained in

position by the downward pressure exerted by d, which is tied with the cord g to the bent sapling h; f is a tough stick bent and solidly implanted in the earth. Between c and a, is another grain, b, which serves as bait. When the bird tries to eat b, c slips sidewise, permitting d to pass through f. This action sets free h, which pulls g, closing the noose around the neck of the prey and lifting it off the ground.

In Codex Madrid some of the saplings have a more or less round object at the foot, which perhaps is simply an indication of the ground, but this is only a possibility (Fig. 121.1, nos. 2, 3, 6; I include also Fig. 121.1, no. 5, which has a different attachment). In Fig. 121.1, no. 7 the black god of hunting supports the sapling on his head. Elsewhere in the codex the sapling is transmuted into a scorpion (e.g., Madrid 48c), which we know to be one of the aspects of the black god through other indications in the same manuscript (Madrid 79a; Thompson 1950:76, 77).

For the capture of quadrupeds this trap cannot be used as it is, but there are many ways in which the trigger can be placed horizontally (as in Fig. 121.1, no. 9). It can be set on the path used by the animal, so that when it is sprung it will catch the animal by the leg, as in Figs. 121.1, nos. 1, 2, and 3. Gann (1918:24) mentions another snare from Maya territory. His description, which is not very clear and is not illustrated, runs as follows:

“... A path frequented by game in going to and from watering places is found; along this is dug a shallow trench opposite a good springy young sapling; two stakes are driven in, one on each side of the trench, the one farthest from the tree being crooked at the top. A piece of henequen cord, provided with a noose at one end, and with a stick long enough to extend from one stake to the other firmly tied by its middle above the noose, is attached to the top of the sapling by its other end. The sapling is then bent down and held in place by the stick above the noose, which is fixed lightly between the crook in one stake opposite to it, the loop hanging suspended between the two. Lastly, a number of sticks and leaves are scattered lightly over the trench and beside the stakes and loop. Animals coming along the run are very apt to put their necks in the loop, and by pulling on this, to release the cross stick, whereupon they are immediately suspended in the air by the jerking back of the bent sapling. Animals of all sizes, from rabbits to tigers, are caught in traps of this kind...”

This description is very useful because, I think, it explains very neatly the element at the right of the tree in Fig. 121.1, no. 3, as the trench above mentioned. A foot of the deer is in it. This device has commonly been understood as “running water.” I do not

accept this interpretation; I believe it means “a cavity in the ground, a hole,” and in a future paper I shall discuss this matter in some detail.

Deadfalls. There are two illustrations of these in Codex Madrid, and in both of them an armadillo is the prisoner. One is drastically simplified (Fig. 121.1, no. 11), but the other (Fig. 121.1, no. 10) is drawn with sufficient detail to permit a safe identification with the Tzutujil trap in Fig. 121.1, no. 9.

This trap is basically a cage with a falling roof, open at the two shortest opposite sides. The bars c are partially suppressed at the front of the drawing to expose the mechanism. The Maya draftsman also took the same measure in order to show the captured animal.

The trigger system of this trap is based on the same principle of the snare trap. The stick j, which has the bait k tied to its center, is precariously supported by the pressure exerted through it by h, against one of the bars c at the point m. A cord g connects h to the lever f. This lever f rests on the stick b, supporting one end of the board n, which is weighted with several heavy stones s. The other end of n is supported by the other lever f', which is simply put under f. When the animal which may enter at either end tries to eat the bait, is caused to slip out of position. This unlocks h, causing, by the release of the levers, the loaded board to fail upon the intruder.

Once the trap closes, it is evident that the levers may look as in Fig. 121.1, no. 10. The recognizable elements of Fig. 121.1, no. 10 are marked with the same letters as in Fig. 121.1, no. 9. In a future paper I shall discuss the important point that the stones on top of the trap are represented by Cauac glyphs.

Pitfalls. There is only one pitfall illustrated in Codex Madrid (Fig. 121.1, no. 2). A hole is dug in the ground large enough to hold the hoped for prey; then, to refine the trap, one or several pointed stakes are erected at the bottom of the pit, and the whole is covered with frail sticks and sufficient foliage. The cavity in the ground is represented as in Fig. 121.1, no. 3, but a pointed stone (the triangular *edz'nab* penetrating the deer), is used instead of the stake, a substitution practiced by other peoples.

Net trap. In Fig. 121.1, no. 13 is reproduced the only one of this type in Codex Madrid. To my knowledge, no net trap from the Maya area which could be correlated with that of the codex has been described. What is clearly a different device is described by Rosales:

“... to catch doves, partridges, etc., they build a small square corral with sticks driven in the ground. It is about 50 cm on each side, and of equal height. They roof it similarly with sticks, and one of the sides, which has been left open,

is covered with a loose net woven of horse hair. The bait is placed inside the corral, near the net. When the bird tries to reach the bait, squeezing his head through the net, he is caught. These traps are placed around the cultivated fields.”

Two New Gallery-Patio Type Structures at Chichen Itza

Karl Ruppert and A. L. Smith

While at Chichen Itza, April 5 to 14, 1954, for the purpose of locating and examining house mounds, we found two new gallery-patio type structures. Thirteen structures of this type are now known at Chichen Itza, but so far none has been reported from any other site.

In looking for house mounds it was necessary to examine inconspicuous terraces and platforms where no large mounds are indicated or identified by numbers on the map (1952, Fig. 151). Thus some areas that had not been seen since the map was made in 1924 were examined with considerable care.

One of the new structures lies 187 m east and 238 m south of the northwest corner of grid 5D. It has been given the number 5D7 (Fig. 122.1a). The other lies 182 m east and 432 m south of the northwest corner of grid 4E and has been given the number 4E3 (Fig. 122.1b).

STRUCTURE 5D7 (FIG. 122.1A).

PLATFORM

Condition. No platform indicated, although a low one may be present and now covered with debris.

GALLERY

Condition. In poor state of preservation. No end walls seen. Gallery indicated by miscellaneous column drums apparently not in position. Small amount of debris. No vault stones seen.

PATIO

Condition. Only traces of walls exposed.

Size. Interior 10.2 m by 11 m. Average thickness of walls 60 cm.

Façade. None exposed.

Interior. Some column drums lying about. Doubtful if any are in position. Diam. of drums 60 cm. Area in middle of patio may be slightly lower than around edges.

SHRINE ROOM

Condition. In poor repair.

Location. On north side of patio.

Size. Interior 2.60 by 3.50 m.

Interior. No vault stones seen.

STRUCTURE 4E3 (FIG. 122.1B)

PLATFORM

Condition. Presence of platform not definitely indicated, although gallery is slightly higher than terrace to west.

GALLERY

Condition. In poor state of repair. End wall at north. This wall turns inward toward south, giving the gallery an interior width of 3 m. No column drums seen. Near south end of back wall of gallery, a fragment of a secondary wall projects 1.6 m.

**a****b**

122.1. Gallery-patio type structures: (a) Structure 5D7, Chichen Itza, plan; (b) Structure 4E3, Chichen Itza, plan.

PATIO

Condition. Fair, with much wall exposed.

Size. Interior 16.5 by 17 m. Walls 70 cm thick.

Façade. None exposed.

Interior. Entrance from gallery, 2.40 m. wide, leads into an antechamber measuring 3.25 by 4.20 m. Opening into the patio proper from this chamber must have been on east side, although jambs of a doorway were not found. Area in center of patio lower than around edges. Some column drums, 50 cm: diam., seem in position.

SHRINE ROOM

Condition. In poor state of preservation. No façade exposed.

Location. On east side of patio.

Size. 3.7 by 4 m.

Interior. No vault stones noted.

Before the discovery of the two new buildings, eleven structures of the gallery-patio type were known at Chichen Itza.

Of the thirteen now known, eight face west, three south, one east, and one north.

No definite information is available as to platforms supporting the new structures, but it seems

likely that the latter rose slightly above the great supporting terrace. In one structure the gallery is definitely of greater length than is the patio; this is the ninth example of a T-shaped building plan, the gallery forming the crossarm of the T.

Str. 4E3 has an antechamber opening from the gallery and built into the patio. Excavations would be necessary to determine whether it is contemporaneous with the gallery or is a later construction. The nearest counterpart to this antechamber is in Str. 5B7. The latter has an antechamber, 2.2 m wide, extending across the entire end of the patio (1943, Fig. 3, d).

Each of the newly identified structures has a shrine room. In Str. 4E3 this room opens from the back wall of the patio, so that it is on the east side of the building. In Str. 5D7 it is on the north side of the patio, making this building the one exception among the nine structures of the gallery-patio type that have shrine rooms. All others have the shrine room on the east side regardless of the direction in which the building faced.

A number of uses have been suggested for these buildings, but so far no definite function can be assigned to them.

Easter Ceremonies at Santiago Atitlan in 1930

Elsie McDougall

The ceremonies of Easter week at the Zutuhil village of Santiago Atitlan are a strange blending of Christian and pagan rites which have briefly been described by S. K. Lothrop (1929a, 1929b) and E. B. Lothrop (1948).

The relatively large village lies at the foot of Volcano Atitlan, on an inlet of the lake of the same name, and is dominated by the seventeenth-century church, once imposing but now badly damaged by repeated earthquakes.

When I reached the village on the morning of Wednesday of Holy Week (April 16, 1930), the main door of the church was open, and a few men were busy on the terrace in front. The crudely rebuilt façade had been freshly whitewashed. An arch of two upright cedar poles and a cross pole had been erected at the foot of the broad flight of stone steps leading to the church, and a second arch stood opposite it on the north side of the plaza. Men were decorating the two arches with boughs of cedar and pine. Twenty-five years ago the village was very isolated, and I was the only outsider at the Easter ceremonies.

The two-roomed municipal building, diagonally across from the church, on the north side of the plaza, was also the scene of activity. The main room, raised a few feet on wooden posts, is the council room and courthouse of the native administration, headed by an elected president, who, as *alcalde segundo*, is, is all dealing with the national administration, subordinate to the ladino *alcalde mayor*, appointed by the national administration. The office

of the *alcalde mayor*, the smaller of the two rooms, adjoins the courthouse.

There was a small crowd, mainly of boys, at the foot of the porch steps, which were directly in front of the door of the main room. The door was open, and native officials were arriving at a brisk pace along the paths radiating from the plaza. Apparently acting officials as well as ex-officios were assembling in the room, arriving individually, invariably serious, some carrying their official wands with them. The door of the large room was at the end, where long benches were set against the wall, and, presumably in preparation for the reception, three or four chairs had been placed between the lines of benches. Officials, as they entered, deposited wands on a rough desk set to one side before ceremonially saluting the native *alcalde* and certain other officials, particularly those of greatest age.

About noon the ladino *alcalde mayor* and his ladino secretary arrived, exchanged greetings with the native *alcalde*, who stood before one of the chairs, and seated themselves. The writer, courteously greeted by the native *alcalde*, sat next to the *alcalde*, who had invited her to enter, and who from time to time volunteered information likely to be of interest. Apparently the *alcalde mayor* was principal guest and had arrived when the assemblage of native officials was about complete. Through the open door, part of the plaza could be seen, and the assembled officials faced the main part of the relatively large room, which had been strewn with fresh pine needles and decorated with cedar and pine boughs.

The ceremony for which the officials had assembled was evidently well organized, and timed for minimum delay. Almost immediately after the entrance of the *alcalde mayor*, a native brought a large palm-woven mat which he quickly unrolled in the center of the floor. The boom of a big drum (*tun*), rapidly crescendo, announced the approach of a procession to the courtroom. Drummer and flutist remained on the porch, as a double file of young men, intent solely on their mission, entered the room at a brisk pace. Each wore the typical Atitlenco wide cotton drawers, European-type coat of indigo-dyed woolen cloth, and palm-woven hat. They bore traditional products of the Pacific lowlands which, according to information volunteered by the *alcalde mayor*, they had been officially commissioned to fetch from the coastal area. The produce was inspected on the return of the young men, and any imperfection punished. The men of one file carried on their shoulders oval brown spathes (sheathed florescence) three to four feet long of *corozo* (cohune) palm. These open during the climactic ceremonies of Easter week, scattering their wealth of thousands of tiny sweet-smelling blossoms of cream white. The men in the parallel file bore on their shoulders large, shallow woven tray-baskets in which were carefully arranged such produce as cacao pods, small bunches of bananas prepared for hanging as decoration, sprays of a bromelia with scarlet flowers (*pie de gallo*), and mahogany-colored squash. The young men promptly deposited deposited their burdens on the floor, at both sides of the part of the room where the mat had been spread, and then departed, again in double file, with big drum and flute at their head.

As the young men departed, other youths of the group employed as court messengers and police (a *uaciles*), starting from the end of the benches, served each of the seated officials, in turn, a small glass measure of *aguardiente*, which the official took and drank at a gulp, without interrupting quiet conversation with a neighbor. The *alcalde* informed me that the drink would be served three times in the course of the ceremony, and that to refuse it would be regarded as a serious breach of courtesy. The invited *alcalde* and secretary conformed to the custom.

This part of the ceremony had scarcely ended when the boom of the drum announced the rapid approach of another procession. This time the two files of young men were a bodyguard for a group of older men, wearing the traditional *gaban* and head scarf, who bore high on their shoulders a queer-looking effigy. This was obscured by fumes from a censer vigorously swung by a man who, facing it, managed to walk backward rapidly. The brownish, rough mask "worn" by the effigy with its slanting eye slits had a

sinister expression. The strange figure was dressed in a coat and the wide cotton trousers of the men of Santiago Atitlan, leather shoes, and several hats, one above the other. Surplus articles of apparel and silk kerchiefs which floated from it, as the bearers rapidly passed, helped to make the figure bulky. This is the effigy known as *Maximon*, described and illustrated by Lothrop (1929). Immediately to the rear of the group followed women dressed in very ample white cotton huipils and with bowed heads. Most of them carried large candles, the upper part of which was sheathed with flowers, a leaf or corn husk protecting the flame; some bore fuming censers. These women were members of the religious sodality (*cofradía*) to which the men bearing the image belonged. The *cofradía* Santa Cruz had charge of the effigy, which was kept concealed in the loft of the lodge except during the two or three days of Easter week before the resurrection ceremony. Rapidly and entirely concentrated on their undertaking, the participants entered the courtroom. The men, as they deposited the effigy in recumbent position on the palm-woven mat were shrouded in fumes from censers. The women (*chahalas*) quickly formed a kneeling semi-circle in front and to the sides of the image. The flickering light of the large candles revealed their heads bent in devotion. The men who had borne the effigy (the *alcalde* qualified them as "priests") remained standing near it, serious and watchful. During the period that the effigy was exposed, native incense was burned before it, including the censer swung by a member of the Santa Cruz *cofradía*, standing, confronting the effigy.

The performance, suggestive of a religious "wake," lasted approximately an hour. During this time, two attendant women twice served a small gourdful of drink (maize gruel one supposes) to each kneeling *chahala* in turn. The drink was immediately taken and consumed without interrupting the attitude of absorbed devotion. During the devotional ceremony a second and third serving of a small measure of *aguardiente* was given to the official spectators. The officials, as far as the writer could see, paid no especial attention to the enacted ceremony, remaining serious, and often conversing in low tone with a neighbor.

The ceremony ended with the prompt, well-organized action which had characterized it throughout. The bearers lifted the effigy to their shoulders (their actions shrouded in incense fumes as, simultaneously, the women arose and, forming a double file, closely followed the bearers of the effigy. The young men of the bodyguard, taking up the fruit or flower offering temporarily deposited on the courtroom floor, flanked the procession. The mat was again

rolled up and carried away, and other young men carried off the pine and cedar boughs which had served as background for the ceremony, to decorate the two temporary arches in the plaza. The big drum and flute again headed the procession, which rapidly crossed the plaza in the direction of the church. Thereupon the assembled officials quietly dispersed after each had courteously bowed with bent left knee before the *alcalde mayor*, and simulated touching his right hand with their lips.

Meanwhile, young men were decorating the two arches on the plaza. The greenery tied to the arches was a background for the offerings brought from the Pacific lowlands. In addition, one or two stuffed rodents were attached. The arch near the northern side was the one under which the procession bearing the resurrected Christ would eventually pass in its course around the village, on *Sábado de Gloria* (Saturday of Holy Week). It was also the arch under which the effigy would be swiftly and unceremoniously carried when the period of devotional worship was at an end.

Custodians of the effigy had secured it to an old post on the terrace of the church, to the (observer's) right of the main entrance. At the base of the post various-sized boulders and stones, including some which had served as club heads in pre-Spanish times, were grouped, in a way suggesting an altar place. Candles, including large ones affixed to the stone club heads, and native incense were burning. The *thurifer*, swinging his censer, was directly in front of the effigy, and custodians were evidently watchful near by. No one approached the effigy closely, but all who entered the church brought it offerings. These included uncommon, relatively costly, articles of dress. Silk kerchiefs, white or purplish red, were most conspicuous, possibly because, attached by one corner to the shoulders or headcloth of the effigy, they floated spectacularly. *Toallas*, such as in everyday life are used by men as neckcloths, sweat cloths, and to lessen the friction of backborn burdens, together with incense, cigars, and candles were among the gifts. Both the candles and incense were burned during the entire period that the effigy remained exposed, and during that period the cornhusks in which the small cakes of resin incense had been wrapped accumulated as a small mound bordering the crude altar. The women *chahalas* also brought offerings of cooked food, which they placed among the candles, flowers, and other offerings (including large cobs of maize brought both by men and women) in front of the image.

During these proceedings, villagers—largely women—drifted quietly into the church for, apparently, more or less brief periods of devotion. All

gave some offering for the effigy to the custodians before entering the church. During the afternoon an increasing number of small boys settled on the wide flight of church steps, some playing a game in which they threw "counters" contrived of disks of crude rubber.

As dusk approached, women and girls, including infants, came in growing numbers from their homes and settled on the steps; more and more candles flickered before the strange effigy on the church terrace, always partly shrouded in incense fumes. Shortly after nightfall, when I left the plaza, the church steps were filled with Indian men, women, and children, including bundle-wrapped babies. The seated throng settled, calmly, quietly waiting below the terrace where, near the main door, the light from numerous candles illuminated the effigy. The custodians were nearby dark forms; the one before the effigy vigorously swung a fuming censer. Evidently a custodian maintained the supply of burning candles and incense. I returned to the plaza about nine o'clock and again shortly before midnight; the scene was unchanged.

By about eight o'clock the next morning (Maundy Thursday), the church steps were largely bare. The custodian group was smaller, but censer swinging and offering of candles and incense before the effigy were continuous. The part of the terrace around the effigy was unsightly; the boulders on which candles and incense continually burned were covered with wax; a mound of discarded maize-husk wrappings added to the litter.

At the far end of the church a few men were polishing silver objects which were on a crude table of refectory-table size. These comprised a large, ornate reliquary, two processional candle holders (battered and bent), and four slim poles attached to the corners of a faded, worn brocade canopy. From time to time, a *chahala* brought to the improvised altar in the church an offering to place in the forefront of the grouped images of saints. The offerings now included extra large maize cobs, some of them with black or speckled black-and-white grains. They were, one may conjecture, prized cobs, the grain intended for the next planting. The church floor had been thickly strewn with fresh pine needles, and pine and cedar boughs decorated the crude wooden pillars of the nave. By midmorning, villagers, mainly women, silently drifted in through the main door, and came to the altar or knelt, more or less briefly, facing it. The women, as they knelt, quickly scooped a small mound of pine needles as cushion for knees.

Toward noon *chahalas*, one by one entering by the front door, crossed the church and went out by

the side door to the corridor. They carried earthenware dishes covered with white cloths. Shortly before midday two younger men quietly cleared the church of occupants (including myself). Evidently the small boys who had scrambled into the cloister patio to watch the activities of the few men were also ousted, and the entrance was guarded, for one of the men remained near the closed main door. Conjecturally, the midday ceremony at the long crude table in the corridor, at which only members of a particular *cofradía* participated, included the enactment of the "Last Supper" and the washing of the disciples feet. One of the *chahalas* who had entered the church and passed through the side door in late morning hours had carried a shallow earthenware bowl and an olla. At San Lucas Toliman I had witnessed, the previous year, the ceremonial enactment of the Last Supper and the washing of feet as an integral element of the Easter week ritual.

In the early afternoon the main door of the church was again open and villagers, mainly women, entered. Youths rang the cracked church bells, and more people assembled. Women and girls wore new huipils, but were barefoot. Some of the women and girls could be identified as from nearby villages, by differences in the decoration of the huipil. Girls were dressed like their mothers, the wrapped skirt cloth secured by a narrow belt until the girls were old enough to tuck in the fold securely at the waist. Some women carried babes and infants, the boys wearing pullover caps covering the face. Some boys of toddler age wore only a shirt.

Within the church unmarried girls assembled in the center of the nave, evidently self-conscious and more amused than serious. Youths, boys, and some men were alongside the broken masonry in what had been the side aisles. Older men entered as small parties; *cofradías* were headed by a leader carrying a staff on which the emblem of the particular saint was mounted. The staffs were elaborately decorated with flowers, *bougainvillea* being most conspicuous. The *cofrades* went directly to the improvised altar, and stood in reverence for a moment while the leader deposited his staff there; the party then settled on knees at the front of the concourse of girls. The church was well filled when three women in the left aisle near the side entrance, directed by an aged man wearing a white head scarf, commenced to sing a service, presumably, in Latin. The girls in the center of the nave were evidently a choir, expected to make the responses, but their performance was irregular, garbled, and not in unison.

When the service had ended, a procession was formed with the image of the Virgen de Dolores, under a canopy, at the head. Onlookers, youths

and boys first, gradually dispersed as the procession passed around the inside of the church. As it returned to the altar, the image of the Virgin was tilted to salute in turn, or be saluted by, the assembled images of the saints before being reinstalled among the group.

It was fairly late in the afternoon when the ceremony ended. At that time the convent (or cloister) patio, the part near the church wall, was the scene of activity which had excited the interest of a crowd of boys. A party of younger men had brought pine saplings and larger trees from a forested tract high on the mountain, and were splitting and trimming them to make huge torches. The flare parts, composed of pine slabs two feet long, were found firmly in position around the tops of the poles, which were, in turn, some five to six feet long. At dusk, when I left, the work of preparing these torches had not ended.

I did not see the ceremony which took place in the main plaza from near midnight to early morning, except for brief periods of observation from the west side of the plaza. It was evident, though, that the pile of pine chips and bark from the torch-making in the convent patio served for a bonfire in which the great torches were lighted. Commencement of the night ceremony was hailed by jubilant shouting in which boys had a large share. It took place along the full length of the north side of the plaza. Two parties, each of four youths, each carried on their shoulders the shafts of a rectangular platform to which the image of a saint was secured, and, starting simultaneously from opposite sides, ran the course swiftly, passing each other midway not far from the courthouse. One of the images was that of a woman, who seemed to me to resemble Mary Magdalene; the other was evidently the one which was familiar to the villagers as St. Nicholas. He wore a peaked hat which men of the village had plaited of green palm strips for this ceremony. As it ran, each bearer group was flanked by torchbearers and followed by a crowd of shouting boys. Each starting place had a rustic shelter presumably constructed for the Lenten processions. Between the running events there were pauses at the shelters. The whole ceremony probably did not last more than two hours.

At about eight o'clock on Good Friday morning, men, presumably of the one or more *cofradías* responsible for the enactment of traditional ceremonies, were quietly and briskly at work in the church. Five or six of them, using white cotton cloths (*toallas*) to cover their hands as they worked, were gradually lowering a large cross, thoroughly wrapped in palm woven matting (*petates*), from the upper part of a wall on the left side of the nave, not far from the

main entrance. Two notched planks served as ladders, and forked poles supported the cross as it was gradually and reverently lowered to the shoulders of the men, who placed it on an improvised support for unwrapping. None of the men touched even the wrapping with bare hands, and it was constantly wreathed in fumes from a swung censer. Each man kissed it before it was slowly unwrapped. With the matting carefully removed, the cross was seen to be painted with heavy sinuous black lines on an olive green ground. The design vaguely suggested a snake's skin.

While the cross was being prepared, some men excavated the hole, in the center of the nave immediately in front of the altar, for "planting" the cross. I could not approach at all closely, and the actions at the hole were shrouded in incense fumes, but evidently two men gradually removed from the whole stones and other filling, which others carried away through the side door of the church. Preparations included the lowering of lighted candles into the hole, and the offering of incantations. Something was poured into the hole, and a fuming censer was lowered for a short time. I could not observe what offering, if any, was placed in the hole, but libations were definitely poured. Throughout the ceremony three chahalas, in voluminous white huipils and each holding a large ceremonial candle in her right hand, knelt facing the hole and the altar behind it.

The erection of the cross, carried on shoulders of men with hands covered with the white cloths, was reverent, as was the attachment of the image of the crucified Christ, bought from the sacristy. A wreath of greenery and flowers was placed on the head of the image, and a long spray across the loincloth.

It was nearing noon before the preparations were completed. By that time the villagers, especially women, had gradually entered the church, the women settling on the floor, girls and younger (marriageable?) women in the center, as on the previous day. From noon onward more and more people came, women with infants and young children, men, youths, boys, until the church was filled to capacity. The men were crowded at the rear; youths and boys climbed onto heaps of masonry and to the tops of broken walls for a view of the proceedings. Late-comers hurried across the plaza. Many men carried crude bull-roarer rattles of various sizes, but kept them inconspicuous, silent. Many of the women held lighted candles. The cofrades, with leader, staff in hand, knelt in the forefront of the assembly, as did the cofradas in their voluminous white huipils. There was notable seriousness and particularly silence when, with the assembly complete and impressively expectant, two men wearing long, wide

white tunics and, as headdress, miter-shaped hats came from the sacristy to the rear of the cross. Using supports already in place, they manipulated what appeared to be a long, rolled white cloth so that it passed under the outstretched arms of the image. Then they slowly detached and lowered the right arm, which loosened, and gradually fell, pointing forward. The lowering of the arm was the signal for a sudden, overwhelming outburst of noise, in which bull-roarer rattles, church bells, and the big drum had part. Simultaneously with the outburst of the noise, the onlookers dispersed, paying no attention to the actual removal of the Christ image from the cross. The atmosphere of tense, quiet watching changed to one of normal behavior, even suggestive of relief. At the end of the church ceremony a procession of men bearing images of saints on litters formed inside the church, but was unheeded by the crowd.

Small boys and youths had already climbed down from their vantage points and were joyously and noisily in pursuit of a group of men who were swiftly running across the plaza, bearing the effigy of Maximón on their shoulders. Evidently the effigy had been loosened from the old post and had been shouldered and borne away by the custodians as soon as the noise announced the evident "resurrection," the vitality, of Christ on the cross. It was out of sight and may have reached the Santa Cruz lodge by the time the ill-organized and largely unheeded church procession started through the main door of the church. It passed under the arch at the foot of the long flight of steps, and crossed the plaza on a brief course, during which some of the relatively few images of saints were taken elsewhere, presumably to the lodges or dwellings of leaders of *cofradías* with special devotion to the image in question. With the departure of the procession, the church door was closed. The celebration for that day had ended in an atmosphere of normality, if not gaiety.

About midmorning of Saturday (*Sábado de Gloria*) villagers, mainly women, came into the church by the main entrance, settling in the nave, in preparation for what was traditionally a service. Apparently other women, accompanying girls presumably their daughters, aged about ten to fifteen years, assembled in the convent patio; then, as a large group including about thirty girls, they entered the church by the side door and settled in the center forefront of the nave.

An old man, apparently reading from an old missal, conducted the service. In the middle of the ceremony there was a sudden, noisy interruption by a group of mirthful boys who ran into the church by the main doorway, brandishing switches. The boys,

not in Atitleco dress and therefore probably not villagers, were immediately ousted by men who had organized the sequence of church ceremonies, and the main door was closed and guarded. Evidently entrance to the patio had already been guarded, and the patio cleared.

At the end of the service, all participants other than the group of girls, who remained kneeling, left by the side door. The women who had brought the girls stayed as a quiet group in the corridor of the patio, as others returned to their homes.

The group of girls remained quietly for possibly a half hour, by which time the church was empty. One of the men organizers of the ceremonies then came to the side door and signaled to them. They arose and, passing in single file to the patio corridor, entered a small, partly restored room to the left of the side door of the church. On entering, each girl kissed a hand of the three most aged among a group of about fifteen mature and older men seated on a bench along one side of the room, and, passing the benches, turned to the open door by which they had entered. At the door stood one of the men, holding a plaited thong whip. As each girl reached the door, she turned her back toward him, hiding her face with upturned arm. The man gently lashed the lower part of her back three times, giving the youngest of the girls the mildest lashes. Clearly the ceremony was taken seriously, for none of the girls smiled. As it was about to end, two or three girls who had evidently been allowed to enter by the patio entrance ran swiftly to the small room, in turn, kissed the hand of the man with the whip, and turned to receive the desired lashes. I was conscious of being watched by the assembled men as I observed the ceremony from the doorway. At its close, after the girls had departed with their mothers, one of the younger men asked me jokingly if I would accept the treatment. I immediately turned my back toward the man with the whip and received three light lashes, to the evident diversion of some of the younger men. Tactful inquiry as to the reason for the ceremony brought as reply, "Para que se

crecen buena." The incorrect Spanish might indicate that the object was to ensure either moral or physical growth.

There were no more ceremonies that day, to the best of my knowledge. Easter Day was a complete anticlimax; there was no activity in the church or in the plaza. On the outskirts of the town a very small group staged an apathetic dance.

The name of the effigy is Relaj-Hacha or Ralaj-Acha, the j having the Spanish aspirate sound. One version was written down for me by the *alcalde segundo*, the other by one of his councilors. I did not hear the effigy referred to as Maximon or by any name in the village, and I should suppose that the term Maximon is of mestizo origin. I find that in my notes I once refer to the effigy as Mom, but I cannot recall where or when I read or heard that name. It is barely possible that two men who overheard my request for the name to the *alcalde segundo* used the name Mom, but I only recollect that they said that the figure was "muy, muy mal."

The *alcalde mayor*, in an aside, told me that a very old and much revered piece of *palo de pito* wood forms the core of the effigy, and this is said to be washed prior to the ceremonies of Easter week by the custodian priests of the Santa Cruz *cofradía*, who then drink the water in which it has been washed. The annual offerings to the effigy are wrapped in mats, I was told, and kept through the year in the same loft of the lodge of the Santa Cruz *cofradía* that conceals the effigy itself.

Rosales (1949), apparently summarizing the ideas held in San Pedro La Laguna concerning the cult among their fellow Zutuhils at Atitlan, reports that Maximon is a saint of the Santa Cruz *cofradía* of Santiago Atitlan. His figure is crudely made of *palo de pito* and is never visible, for it is kept always in a box. At night he wanders around all the towns in the region, wherever he is called. He converses only with shamans and native prayer-makers, and tells them what they must do. He is very much revered by all the people; when there is just cause, he chastises mercilessly (*sin remedio*).

Pottery Specimens from Guatemala II

Robert E. Smith

The thirteen specimens described here belong to the Montano collection, and all, save one (Fig. 124.1a), are in the National Museum of Archaeology and Ethnology of Guatemala. The donor, the late Dr. Hector Montano Novela of Guatemala, was an enthusiastic amateur archaeologist and collector.

The items illustrated are reported to have originated from three different parts of Guatemala: a-f, Ilón, northwestern Quiché; a-j, Panajachel, on Lake Atitlan, Solola; k-m, La Flojera, on the Rio Salinas midway between Delicias to the north and Caribe to the south and not far from the northern border of Alta Verapaz.

Fig. 124.1a-f. Vessels from Ilón, all early Late Classic (Tepeu 1) types save e, which is not familiar to me.

a. Red-and-orange-on-buff deep bowl. *Form:* nearly cylindrical, slightly flaring sides, direct rim, rounded lip, flat base. *Size:* lip diam. 13.6 cm, base diam. 4.5 cm, ht. 14.2 cm, wall thickness 0.4–0.5 cm. *Finish, color, decoration:* interior, smoothed unslipped dark gray; exterior, slipped and polished buff with red and orange decoration consisting of central wall band of vertical stripes and lines, in alternating red and orange groups.

b. Red-on-orange gloss ware deep bowl. *Form:* nearly cylindrical, slightly rounded sides, direct rim, rounded lip, flat base. *Size:* lip diam. 13.6 cm, max. diam. 14.2 cm, base diam. 6.5 cm, ht. 13.6 cm, wall thickness 0.4–0.5 cm. *Finish, color, decoration:* interior, dark (?); exterior, slipped and pol-

ished orange with light and dark red rim band of steps-and-angular-scrolls.

c. Red-and-black-on-orange gloss ware deep bowl. *Form:* nearly cylindrical, slightly recurving sides, direct rim, rounded lip, disc impressed base. *Size:* lip diam. 13.6 cm, max. diam. 14.2 cm, base diam. 7.4 cm, ht. 14.2 cm, wall thickness 0.3–0.5 cm. *Finish, color, decoration:* interior, polished light orange slip; exterior, well burnished orange slip decorated with panels of single standing figure (in profile) carrying standard done in red and black. *Remarks:* an unusual style of figure painting, so far not noted elsewhere.

d. Red-and-black-on-orange gloss ware bowl. *Form:* rounded sides, direct rim, rounded lip, slightly concave base. *Size:* lip diam. 12.4 cm, max. diam. 14 cm, base diam. 6.2 cm, ht. 11.5 cm, wall thickness 0.3–0.4 cm. *Finish, color, decoration:* interior, slipped orange, lightly polished, with 2 cm, broad red rim stripe; exterior, slipped and polished orange with red and black encircling stripes framing a line of birds painted black which form a rim band resting on a line of black dots. *Remarks:* comparable in shape and ware to two vessels from Xacbal close to Ilón (Termer 1931, Figs. 9, 10).

e. Incised black tripod bowl. *Form:* recurved sides, parenthesis rim, rounded lip, flat base, 3 hollow feet (all broken off). *Size:* lip diam. 14 cm, max. diam. 1 cm, body ht. 10.1 cm, wall thickness 0.3–0.5 cm. *Finish, color, decoration:* interior, weathered, may have been unslipped; exterior, slipped and polished black with central incised band consisting of cross-

124.1. Pottery specimens from Guatemala II.

hatched panels. Remarks: a most unusual specimen. The parenthesis rim in Yucatan is usually a late Mayapan or more recent ceramic feature.

f. Red-and-black-on-orange gloss ware bowl. Form: rounded sides, direct rim, rounded lip, disc impresse base. *Size*: lip diam. 14.2 cm, max. diam. 15.4 cm, base diam. 7 cm, ht. 11.1 cm, wall thickness 0.3–0.4 cm. *Finish, color, decoration*: interior, slipped and lightly polished part way down with 2 cm red rim stripe; exterior, slipped and polished orange with red and black encircling stripes framing a line of birds painted black which form a rim band. *Remarks*: same as d.

Fig. 124.1g–j. Specimens from Panajachel, of various types.

g. Unslipped buff-colored, hollow, moldmade Classic type figurine. Form: standing warrior holding shield on left arm; a whistle with two stops and mouthpiece at rear base. *Size*: ht. 13.7 cm, max. (depth) at base 5.1 cm, wall thickness 0.3–1.0 cm. *Finish color, decoration*: smoothed with carved and applied adornment and modeled features all reproduced in mold.

h. Dark brown cylinder tripod. Form: outcurving sides, both rim and basal moldings, rounded lip, slightly convex base, three hollow cylindrical feet. *Size*: lip diam. 18 cm, base diam. 16.2 cm, bowl ht. 8b cm, overall ht. 13.5 cm, wall thickness 0.4–0.5 cm. *Finish, color, decoration*: interior and exterior, slipped and polished dark brown; exterior, incised braid band just below rim molding, negative painted central wall band of circles and vertical lines, applied death's-heads on basal molding.

i. Reddish brown cylinder tripod. Form: outcurving sides, basal molding, direct rim, rounded lip, flat base, three hollow rounded-bottom cylindrical feet.

Size: lip diam. 18.2 cm, base diam. 16 cm, bowl ht. 10.1 cm, overall ht. 15 cm, wall thickness 0.4–0.7 cm. *Finish, color, decoration*: interior and exterior, slipped and d dark brown; exterior, vertical body fluting, applied screwheads on basal molding.

j. Black cylindrical bowl. Form: slightly rounded sides, direct rim, rounded lip, flat base. *Size*: lip diam. 12.4 cm, base diam. 7 cm, ht. 9.2 cm. *Finish and color*: interior upper wall and exterior, slipped black and polished.

Fig. 124.1k–m: Sherds from La Flojera, all Late Classic types.

k. Red-and-black-on-cream basal-flange tripod (?) dish. Form: flaring sides, thickened rim, rounded lip, terraced flange. *Size*: not measured. *Finish, color, decoration*: interior, slipped cream and polished, geometric decoration in red and black; exterior, unclipped and unpolished.

l. Red-and-black-and-white-on-orange basal-flange tripod (?) dish. Form: flaring sides, thickened rim, rounded lip, notched basal flange. *Size*: not measured. *Finish, color, decoration*: interior, slipped orange and polished, two wall bands including "dress shirt" and step-and-scroll designs in upper band and "comb" and "double-yoke" elements bracketing a cartouched element in lower band; exterior, unclipped and unpolished, rim groove and diagonal slashes between flange notches.

m. Red-and-black-on-orange basal-ridge tripod plate. Form: flaring sides, slightly everted rim, rounded lip. *Size*: lip diam. 32.4 cm, body ht. 4.8 cm, wall thickness 0.4–0.7 cm. *Finish, color, decoration*: interior, wall band of bracketed glyph-like cartouches separated by diagonally hatched triangles, floor design badly weathered; exterior, unclipped and unpolished.

Pottery Vessels from Campeche

Robert E. Smith

In 1949 I paid a brief visit to the small but well-organized Archaeological and Ethnological Museum of Campeche, Mexico. Among the many handsome Maya objects on exhibit, the nine pottery vessels here illustrated were of special interest to me. The director of the museum, Raul Pavon Abreu, was most co-operative. He not only supplied the information that all these specimens, save Figure 125.1e (from the Chenes area), were found in a single mound bisected by the highway from Champoton to Escarciga, a mound later completely destroyed, but was kind enough to have the museum artist, Hipolito Sanchez, make paintings of the vessels.

All the vessels but f belong to the Lowland Maya Late Classic tradition. Five examples (a, c, e-i) are decorated with figure painting, and in two of these (c, i) the painting depicts pottery vessels, unfortunately without sufficient detail to suggest an exact time of manufacture or place of origin. The brown ware tripod bowl (f) with gouged-and-incised panels may be a type of Slate ware, but having seen it only under glass, I cannot be certain.

The misfortune of the key's not being available to open the cases prevented an inspection of the bowl interiors and vessel bases. In spite of this lack of data, it is considered best to make this material available with the information at hand.

Fig. 125.1a. Red-and-black-on-orange bowl. *Form:* nearly vertical sides, rounding to flat base, direct rim, pointed lip. *Size:* lip diam. 17 cm, base diam, 8 cm, ht. 10.2 cm, wall thickness 0.5-0.9 cm.

Finish, color, decoration: exterior, slipped orange and well polished, below black basal stripe the wall is gray from firing, above the black basal stripe is a broad band of alternating red and black birds with long beaks.

b. Black-on-orange (buff?) deep bowl. *Form:* vertical upper wall gently rounding to flat base, direct rim, rounded lip. *Size:* lip diam. 17.5 cm, base diam, 6 cm, ht, 9.5 cm, wall thickness 0.5-0.7 cm. *Finish, color, decoration:* exterior, upper wall slipped orange, lower wall buff color, upper wall decorated with band of "sausages" and related elements.

c. Polychrome ring-based bowl. *Form:* slightly recurving sides rounding to ring base. *Size:* lip diam. 16.7 cm; base diam. 11 cm, ht, 9.2 cm, wall thickness 0.5-0.8 cm. *Finish, color, decoration:* exterior, slipped cream to buff and polished, main wall decorated with encircling band consisting of alternating pottery bars and seated human figures separated by vertical fish-scale-like bands.

d. Black-on-orange deep bowl. *Form:* vertical upper wall gently rounding to flat base, direct rim, rounded lip. *Size:* lip diam. 18.6 cm, base diam. 6 cm, ht. 10.8 cm, wall thickness 0.5-0.8 cm. *Finish, color, decoration:* exterior, slipped orange and polished, upper wall decorated by *encircling band* with alternating ilhuictl-like and unknown symbols.

e. Red-and-black-on-orange bowl with solid disc base. *Form:* vertical sides rounding to base, direct rim, rounded lip. *Size:* lip diam, 15.5 cm, base diam. 10.5 cm, ht. 10.6 cm, wall thickness 0.6-0.8 cm. *Finish, color, decoration:* slipped orange and polished,

125.1. Pottery vessels from Campeche.

decorated with horizontal encircling black and red lines, stripes, and bands, the upper band containing a diamond and triangle pattern, the lower a succession of black ovoids;

f. Brown (possibly Medium Slate) tripod ring-stand, jar. *Form*: globular body, outcurving medium high neck, direct rim, three solid slab feet joined to ring-stand. *Size*: lip diam. 12 cm, base diam. 11.5 cm, ht. 11 cm. *Finish, color, decoration*: exterior, slipped and polished, decorated with a gouged-and-incised glyph band and two somewhat differently designed panels, each enclosing a central human head surrounded by a variety of elements. *Remarks*: this is to me a unique specimen in both form and panel design.

g. Red-and-orange-and-black-on-buff tripod plate. *Form*: flaring sides, wide everted rim, rounded lip, flat base, and 3 hollow conical feet with single circular vent in each. *Size*: lip diam. 27.8 cm, base diam. 22 cm, body ht. 4.6 cm, overall ht. 6.1 cm. *Finish, color, decoration*: interior, slipped buff and pol-

ished, everted rim decorated with geometric band, floor has red deer shown with black details.

h. Red-and-black-on-orange tripod plate. *Form*: outcurving sides, direct rim, pointed lip, slightly concave base, and 3 hollow cylindrical feet with two circular vents in each. *Size*: lip diam. 31 cm, base diam. 24 cm, body ht. 4.8 cm, over all ht. 9.6 cm. *Finish, color, decoration*: interior, slipped orange and polished, re rim band of solid black rectangles separated by two vertical black lines, red and black design on floor too weathered to decipher.

i. Red-and-black-on-orange tripod plate. *Form*: outcurving sides, direct rim, rounded lip, slightly concave base, 3 cylindrical feet with rounded bottoms and a single ovoid vent in each. *Size*: lip diam. 32 cm, base diam. 24.4 cm, body ht. 4.8 cm, overall ht. 9.6 cm. *Finish, color, decoration*: interior, slipped orange and polished, red rim and floor stripes framing red and black glyph band, floor has seated human figure holding a large plate, all done in red and black.

Selected Pottery from Tabasco

Heinrich Berlin

The pottery and other artifacts here illustrated were found during two field seasons of survey of Tabasco in 1953 and 1954. For the "setting" of the specimens and the location of the sites, the reader is referred to Berlin (1953). Most of the material excavated during the two seasons consisted either of untempered Fine Paste wares or of pottery closely associated with them, and will be published separately. There remained, however, some pieces which because of their peculiar shapes or because of their distribution should be placed on record. Capitalized color readings are taken from Ridgway (1912) and are followed by Munsell equivalents (Hamly 1949). Drawings are by Alberto Garcia Maldonado. The scale of d, j, k is 1/8, that of the rest is 1/4.

FIG. 126.1A-L: BELLOTE, TABASCO.

a. Plan of explored mound with stucco-decorated walls on top. A and B indicate later and earlier phases of substructure. I, II, III show successive phases of temple platform. See Berlin (1953:107-08).

b. Dish. Dark brown paste, heavily tempered. Dark red all-over slip, well polished. Wide everted rim with one preslip groove. Period: pre-Classic.

c. Large cylinder. Light brown crumbly paste, medium fine textured, with temper. Light brown all-over slip. Preslip grooves encircle upper wall; below these the wall is decorated with geometric designs in medium to coarse incising. This decoration is reminiscent of the blackbrown fine and coarse incised wares of Kaminaljuyu (Shook and Kidder 1952). Period: pre-Classic.

The two foregoing pieces (Fig. 126.1b, c) were in Pit 2, dug through the uppermost terrace near the southwest corner. Six successive terrace floors of lime cement, with a total depth of 20 cm, overlay a solidly packed shell fill in which were these two vessels. The cylinder was upside down, the red dish inverted over it.

d. Large deep vessel. Untempered fine orange Salmon-Buff (7.5YR 7.8/6.0) paste. Exterior probably slipped in same color, but too weathered to be certain. Short 0.3 cm-deep vertical gashes around the base. Period: uncertain. Small bowl. Tempered brown paste. All-over polished slip in the same color. Gray to black firing clouds on the interior. Period: uncertain.

e. Large restricted orifice vessel.

f, h. Flaring-sided bowls.

i, j. Cross and longitudinal section of oval basin.

k, l. Longitudinal and cross section of cover for oval basins.

The last five specimens (e, f, h-l) belong to very thick-walled, pinkish-red or brick colored ware with medium textured, tempered paste. Surfaces are cursorily smoothed and apparently have an all-over white lime coating, perhaps a slip. More than twenty-two of these vessels and covers, together with those shown in d and g, were in an incompletely excavated grave (Pit 3) in front and at the base of the pyramid. Normally each basin had a cover, and each of the large deep vessels of the form shown in a had a bowl with flaring sides inverted over it as a cover. In other examples two flaring-sided bowls were lip

126.1. Selected pottery from Tabasco.

to lip. Nothing was inside these vessels. With them were at least two skeletons, one of which was of a female between 21 and 35.

The age of these pieces is uncertain. Stratigraphically they were sealed by the uppermost of three floors which joined a vertical terrace wall (shown as Line A in Pit 4) of the last phase of the pyramid. A basin with cover, similar to those just described, was found at San Jose, British Honduras (Thompson 1939, Fig. 37) and was assigned either to San Jose I or to San Jose II, that is to say either to pre-Classic or to Early Classic.

FIG. 126L, M, N, U: EL TREN, CHIAPAS.

m. Footed polychrome bowl. Rim diameter 24 cm. Tempered paste of fine texture. Dark gray core with light brown edges. Designs in black and orange (shown in oblique hatching) painted on a primary all-over cream slip. The number of feet is uncertain (a weathered polychrome tetrapod has been found at the site). Period: Early Classic.

n. Flaring-walled bowl. Rim diameter 40 cm. Same paste as above. Primary all-over cream slip. Mars Orange (10R4.5/10.0) band (shown by narrow oblique hatching) covers the lip. Exterior: black lines on cream. Interior: secondary orange color (shown by wide oblique hatching) with black horizontal lines below the lip. Period: Early Classic.

u. Incised round bowl. Rim diameter 18 cm. Medium fine textured, light brown, tempered paste. Well polished Orange-Rufous (2.5R5.0/10.0) all-over slip. Darker areas on interior bottom and exterior apparently due to firing. Pre-slip incised decoration. Period: Early Classic.

Surface sherds (*u*) and the material from a small test pit (*m*, *n*) were exclusively Early Classic.

FIG. 126.1S, T: ISLA DE CHABLE, TABASCO.

s. Sherd of composite silhouette bowl. Rim diameter 21 cm. Medium to coarse textured, brown, heavily tempered paste. Exterior and interior slipped a mottled Vinaceous-Rufous (10R4.5/9.0) color. Slip is conspicuously crazed. All surfaces bear a glossy finish, waxy to the touch. Period: pre-Classic or Early Classic (?).

t. Heavy-walled bowl. Fine dark gray untempered paste. Because of weathering one cannot say whether the bowl was once slipped. The upper part around the rim is whitish to light gray, the remainder of the vessel uniformly gray. Period: pre-Classic to Early Classic.

Both specimens were collected from a beach. Ceramic types similar to these have been found by Drucker at Cerro de las Mesas (1943a:44), Tres Zapotes (1943:59), and La Venta (1952:92). Our specimen, however, is different in shape, color, and temper. Only at La Venta did Drucker find an untempered Fine Paste Gray-Blackware with white (mottled) rim. It would seem that we are dealing with a specific technique of firing rather than with a uniform ceramic ware. This firing technique has been found, as far as I know, only in southern Veracruz and northwestern Tabasco.

FIG. 126.10–R. HAND MODELED PRE-CLASSIC FIGURINE HEADS.

o. Slipped (?), light brown, medium textured paste. Hollow. Eye formed by two opposed lateral gashes with blunt tool, and a central punch for the pupil which penetrates to the hollow interior. Head damaged around the mouth. Surface collection, Bellote.

p. Weathered. Tempered paste, fine textured and buff colored. Solid. Two lateral and one central punch to form eye, as in *o*.

q. Buff ware as above. Solid. Distinct ear plugs. Incisions above right eye giving bonnet effect, but top broken off.

Heads in *p* and *q* were found by Sr. Manuel Pavon Jasso at Finca Tierra Blanca, near Emiliano Zapata.

r. Unslipped buff ware as above. Solid. Remarkably Olmec in style. Said to have come from near Emiliano Zapata.

FIG. 126.1V. STONE ARTIFACTS.

The point of black obsidian (0.8 cm thick) is from El Tortuguero, Tabasco; the rest, of opaque gray-white flint, are from Tiradero, Tabasco.

Chronological Decipherments from Uaxactun, Naranjo, and Ixlu, Peten

J. Eric S. Thompson

Stela 14, Uaxactun, is broken in many pieces, and Morley (1938:1:215) despaired of wresting its dedicatory date from it. It is difficult to make much of the published fragments (Morley 1938:1, Pl. 64; note that d is inverted). On stylistic grounds, Morley favored a late placement, and very tentatively suggested the position 9.19.0.0.0. Proskouriakoff (1950:125, 197) saw no late traits and opted for a date around 9.1.0.0.0. The reading here advanced was made before I had consulted Proskouriakoff's study; its close agreement with her stylistic dating of the monument is yet another confirmation of the accuracy of her system, were such needed, and, reciprocally, Proskouriakoff's dating strengthens the proposed decipherment.

While sorting papers left by Morley I came across a sheet of tracing paper with drawings by him of the glyphs on three fragments of Stela 14 (Fig. 127.1). The fragments correspond to those in the photographs of this stela lettered c, d, and perhaps part of that labeled b, on plate 64 of Morley's book. For some reason these drawings were not included in that work.

Examining afresh Morley's plate 64c with the aid of the newly discovered drawing, I concluded that the last glyph was, in all probability, the form of the half-period glyph in which the shell element is prefixed to, not infixed in, the completion element with "down-balls" affix (Thompson 1950, Fig. 32).

The superfix of the penultimate glyph is almost surely that corresponding to the month Cumku, and the defective coefficient of two dots can safely be

restored as 3. The partly destroyed glyph which precedes this is a day sign, and must be Ahau if this is a half-period ending. The coefficient, as Morley noted, is 7. The whole, therefore, reads (9.13.10.0.0) 7 Ahau 3 Cumku, half period.

There is a distance number on this same fragment 3.?.?. The uinal coefficient is gone; that of the kin is 4, 9, 14, or 19. At Al-B1 Morley saw a day sign with certain coefficient of 5 and a month sign with coefficient of 2 or 4, the former being preferable. In the photograph it is hard to make out details. Possibly the arrangement is:

(9.13.6.17.6)	5 Cimi 4 Cumku
3.0.14	
9.13.10.0.0	7 Ahau 3 Cumku

This reconstruction, except for the period ending, is decidedly dubious, as is the 9 Ahau 18? which Morley saw at B9-B10 (I find it impossible to identify in the photograph the glyph blocks in question).

On the reasonable assumption that 9.13.10.0.0 was the dedicatory date of Stela 14, we now have one certain date to fill the puzzling gap from before 9.10.0.0.0 to 9.1.0.0.0 in the Uaxactun (and Tikal) sequence.

For Stela 28, Naranjo, Morley (1938:2:104-110) hesitatingly offered a series of readings, but he made it clear that he had doubts about his interpretation of the framework of dates, as, indeed, he might in view of the damaged condition of the text. His sequence of dates depends entirely on the correct decipher-

ment of the IS. The most serious objection to his suggested reading of 9.12.4.10.2 1 Ik 10 Pax is that the lunar data do not agree with it. Morley thought that they did, because, falling into a strange aberration, he supposed that the lunar record of 2D represented a count of 12 days, whereas, of course, it marks a moon age of 2 days. The date in question calls for a moon age of about 14 days. Andrews (1951:135) has proposed the reading 9.11.4.10.2 3 Ik 5 Zip as offering agreement between IS and lunar data, but expressed doubt as to its reliability by adding a question mark.

The lunar series is not easily read, but Glyph C appears to have a coefficient of 3 and Glyph D of 4 (Glyph Blocks D5, C6), although Morley read 5?C 4D, a reading accepted by Andrews. Little can be made of Glyph X. For the IS, I should suggest the reading 9.14.4.7.1 1 Imix 9 Zip. Stela 30 gives a moon age of 4C 4D for the IS 9.1.3.0.0 7 Ahau 18 Kankin. This date is 501 days (17 moons less 1 day) before the suggested reading of the IS of Stela 28, and conforms to the period of uniformity. One would, therefore, expect a period-of-uniformity moon age of 3C 3D for 9.14.4.7.1. As the reading appears to be 3C 4D, the agreement is very close. Eight moons of 30 days and nine of 29 days would span the interval of 501 days and produce readings of 4D in both texts. The proposed reading of the IS finds support in other dates in the text. I should propose the following arrangement:

C1-C4, C8, C13	9.14.4.7.1	1 Imix 9 Zip
	3	
D13, C14	9.14.4.7.4	4 Kan 12 Zip
E4	5.4	
F4, E5	9.14.4.12.8	4 lamat 16 Mol
F9	1.13	
E10, F10	9.14.4.14.1	11 Imix 9 Yax
E14	2.16	
F14, E15	9.14.4.16.17	2 Caban 5 Mac
G8	12	
H8, G9	9.14.4.17.9	1 Muluc 17 Mac
I11, J11	5.0.11	
J12, I13	9.14.10.0.0	5 Ahau 3 Mac
I14, J14	1.5.0.0	
I15, J15	From anterior date (suppressed 9.13.3.0.0) count forward to	
A1, A2	(9.14.8.0.0)	13 Ahau 13 Mac

For a review of problems involved and the many alternative readings, the reader is referred to Morley's

127.1. Part of inscription, Stela 14, Uaxactun.

discussion (1938:2:108–109). The date 9.14.4.12.8 4 Lamat 16 Mol is 1 day after the IS of the companion Stela 31, which also commemorates 9.14.10.0.0. The final distance number of 1.5.0.0 and the date on the front of the monument are shots in the dark. I assume a suppressed 9.13.3.0.0 and numerical classificatory elements which make the distance number look like 6.10.0.0. The date 9.13.3.0.0 was obviously important at Naranjo. As its first katun anniversary is given on both Stelae 29 and 30, in the latter case as an IS, it is not illogical to expect to encounter its 25-tun anniversary. At least, the two final glyphs on the back of the monument appear to be the posterior and anterior date indicators, and should, therefore, connect the last record on the back of the monument with the 13 ? 13 ? CR on the front of the stela.

In passing, it should be noted that the distance number on Stela 31 at 16, 17 is not 8.0.2.0, as Morley believed, but 8.0.0.0. The arrangement is:

I6, I7	8.0.0.0	
J7, I8, J8	9.6.10.0.0	8 Ahau 13 Pax Seating Haab?
I13-J14	9.14.10.0.0	5 Ahau 3 Mac, completion of haab, half period

Katun anniversaries are by no means unknown at Naranjo. Apart from those commemorating 9.13.3.0.0, Morley has noted that 9.13.1.3.19 5 Cauac 2 Xul, an IS on Stela 21 and declared also on Stela 22, has its katun anniversary on Stela 30, where the CR (9.14.1.3.19) 3

Cauac 2 Pop is followed by a completion glyph in the form of a hand followed by a weathered glyph which presumably records 1 katun.

On the Hieroglyphic Stairway the best reconstructions of two dates suppressed or, more probably, on missing blocks are 10 tuns apart. Morley's suggested readings are:

9.9.17.11.14	13 Ix 12 Zac
9.10.7.11.14	12 Ix 2 Ch'en

Stela 22 records the date 9.13.1.13.14 5 Ix 17 Muan, and the katun anniversary of this, 9.14.1.13.14 3 Ix 17 Yax, appears on Stela 30. The glyph block (G3) immediately following this date, where one might expect to find a record of the first katun anniversary, is not legible. The various katun anniversaries on Stela 25 have received comment (Thompson 1950:195). It is interesting to note that on Stela 3, of much later date, a distance number 7.9.3.15 leads back to 9.6.12.0.4 4 Kan 7 Pax, which is given on Stela 25 as the first katun anniversary of 9.5.12.0.4. This fact not only confirms a brilliant piece of decipherment by Morley, but also warns that these occasional retrocessions of several katuns into the past do not necessarily record calculations made at the time the monument in question was to be erected.

The priests of Naranjo seem to have sought occurrences of 13 Ahau. We find among Morley's readings: 9.14.2.4.0 13 Ahau 3 Uayeb, 9.19.4.10.0 13 Ahau 13 Mol, and 9.19.9.15.0 13 Ahau 8 Zip I have suggested the reading 9.14.8.0.0 13 Ahau 13 Mac for the front of Stela 28. This is not only the 25-tun anniversary of the important date 9.13.3.0.0, but it also recovers the position 13 Ahau, a detail that fortifies the proposed decipherment.

The round altar at Ixlu is associated by Morley (1938:3:443) with Stela 2, although in the map of the ruins prepared by Blom (1926–1927, Pl. 210a) it is shown immediately in front of Stela 1. Morley associated it with the nearby Stela 2 because he thought that the two monuments recorded the same date, 10.2.10.0.0 2 Ahau 13 Ch'en. He was led to that conclusion partly through his failure to recognize that the element of two circles with a cross between was an affix indicating expiration, and not, as he supposed, the numerical coefficient 2.

This was attached to the sign for 10 tuns, and he supposed the whole should be read as 2 katuns, 10 tuns, marking the end of 2 katuns and 10 tuns after 10.0.0.0.0. Actually, the coefficient of Ahau in B1 (Blom 1926–1927, Pl. 159a) cannot be 2, as Morley supposes, for the two dots still visible occupy only half the height of the day sign. The coefficient must be 4, or just conceivably 3. The month sign is clearly the head of an animal, either that of Xul or the personified form of Kankin. The "ak" suffix shows that this must be Kankin, for on the monuments that suffix occurs only with the month signs Pop, Zec, and Kankin (in Codex Dresden also with Kayab). Glyphs B2 and A3 inform us that the date marks a half period and the completion of 10 tuns. With further redundancy, B3 adds that the date marks the completion of a tun. The variant of the expiration affix with the X element already mentioned did not come into use until after 9.17.0.0.0, and so we have an additional check on the decipherment. The only decipherment that will meet these conditions is 10.1.10.0.0 4 Ahau 13 Kankin.

This date is the same as that of Stela 1, with which the altar is associated by position. There can, accordingly, be not the slightest doubt that this monument is the altar of Stela 1 and carries the date 10.1.10.0.0 4 Ahau 13 Kankin.

Notes on the Use of Cacao in Middle America

J. Eric S. Thompson

INTRODUCTION

Cacao attracted the keen interest of the first Spaniards to reach Middle America partly because of its importance as a beverage, partly because of the unusual method of cultivation dependent on the shade-giving "mother" tree, but principally because it was to Europeans, forgetful of the 'origin of the Latin petunia, that novelty, a perishable currency. Thus, in one of the earliest (1525) accounts of the fruit we meet with a philosophical attitude: "But it is very needful to heare what happie money they use, for they have money, which I call happy, because for the greedie desire and gaping to attaine the same, the bowelles of the earth are not rent a sunder, nor through the ravening greedinesse of covetous men, nor terrour of warres assayling, it returneth to the dennes and caves of the mother earth, as golden, or silver money doth. For this groweth upon trees" (Martyr 1612, Dec. 8, Ch. 4).

There are many accounts in sixteenth- and seventeenth-century writings of the cultivation of cacao and of the preparation of chocolate. One of the best is that of Oviedo y Valdes, written before 1555 (1851-55, Bk. 8, Ch. 30). Thomas Gage (1677:238), the renegade Dominican friar who lived in Mexico and Guatemala from 1625 to 1637, has left a lengthy account in well flavored English of the period. In all discussions of cacao it is essential to distinguish between the pod and the individual bean, of which there are nearly thirty in each pod. The usual Spanish name for the pod is *mazorca* (used also for an ear of maize); the bean is called *almendra* (almond).

CACAO AS CURRENCY AND ARTICLE OF TRIBUTE

Cacao was an important article of trade and of tribute, largely because conditions favorable for its cultivation are not found in many parts of Middle America, for it requires a damp climate, shelter, and low altitude. Large areas, such as the Mexican plateau, the highlands of Guatemala, and Yucatan, are unsuitable. Typical of its importance in commerce are statements that Yucatan exchanged salt, cotton textiles, and slaves for the cacao of Tabasco and Veracruz (Tozzer 1941:94-95) and of Honduras (Oviedo y Valdes 1851-1855, Bk. 32, Ch. 8). Much cacao was shipped in ancient times from Soconusco to the Mexican plateau, and even from Guatemala (Sahagun 1938, Bk. 10, Ch. 13). With the decline in the Soconusco plantations, a few decades after the Spanish conquest, more cacao was brought to Mexico from Guatemala (Ponce 1875:1:293; Vasquez de Espinosa 1942, §638). Merchants went from Xiu territory to the Rio Hondo and Bacalar to buy cacao, which probably came from the banks of the New River or even the Belize River (Roys, in press).

As an article of tribute, cacao is prominent in the tribute list of Codex Mendoza. Soconusco paid 400 loads to the Aztec confederacy (Codex Mendoza 1938:47). The total from all provinces was 980 loads each year (Molins Fábrega, 1954-1955). According to Lopez de Cogolludo (1867-1868, Bk. 4, Ch. 3), the scant tribute paid to Mayapan in its period of dominance included cacao sent by the area that produced it. Unless Chetumal, a large producer of cacao, was

subject to Mayapan, as Roys believes, this must have been the Province of Cupul, where a certain amount of cacao was grown in the many cenotes in that region (Sanchez de Aguilar 1892:98); north-west Yucatan appears to be too dry for its successful cultivation. Traditionally, the migrating ancestors of the Cakchiquel paid cacao as tribute to Tula, whence they had migrated (*Annals of the Cakchiquels* 1953:48). In colonial times cacao continued to be an article of tribute (*Relation de Zapotitlan* 1579). In Tabasco alone the 1660 Indian tributaries who had survived the Spanish conquest and its accompanying plagues paid annually about 1500 loads of cacao to their new masters, considerably more than the Aztec confederacy received from all its tributaries (*Relaciones de Yucatan* 1898–1900:11:330–41).

There is no published information on the worth of cacao in pre-Colombian times, but in a paper now in press Scholes and Adams give information on tribute values of cacao in terms of *mantas*; for the colonial period there is a considerable body of material. Cacao was counted by beans and in the vigesimal system. The standard measure was the load (*carga*) a man carried, and this consisted of 3 *xiquipils* (each of 8,000) of beans, that is to say 24,000 beans. A *xiquipil* comprised 20 *zontlis*, each of 400 beans. The *carga* of maize in present-day Yucatan is approximately 90 pounds, but the *carga* of cacao weighed only a little over 50 pounds (2 *arrobos*), although in pre-Colombian times the weighing scale was unknown. Cacao transactions were principally by counting, although cubic measures presumably were used for handling large quantities. The use of measures but absence of scales in the market place of Tenochtitlan was remarked by Cortes (1908:1:259).

Rates of exchange in terms of Spanish currency have fluctuated with the centuries. Motolinia (1914, *Trat.* 3, Ch. 8), who wrote in 1541, informs us that a load of beans was then worth 5 to 6 gold pesos in the center of production. A gold peso was the equivalent of 12 ½ silver reales (the ordinary *real*, 8 of which made a peso). At the higher price this works out at nearly 9 ½ silver pesos for a load, and 320 beans for a real. That was the price in Soconusco, Guatemala, or Tabasco; the price in Mexico City was nearly double that, and one can suppose that it was about 16–18 pesos.

The probanza of the cacique of Xicalango, dated 1552 (Archivo General de Indias, *fide* Berlin 1956:110), lists the tribute as 40 *xiquipils* of cacao, or its equivalent of 100 pesos. This gives a rate of 7 ½ pesos for a load. On the assumption that these are the usual silver pesos, this rate is somewhat lower than that which Motolinia gives. Moreover, Xicalango, although an important depot for Tabasco and Yucatan

trade, was somewhat distant from the cacao plantations, whence the crop presumably was brought by water. I have seen cacao plantations near Teapa, from which point Xicalango must be about 250 km. distant by water, so that a haulage charge is to be added to the plantation price.

The Quijada papers (Scholes and Adams 1938:2: 104, 214, 217) throw some indirect light on cacao transactions. One of the charges against Diego Quijada, Alcalde Major of Yucatan, was that he, together with a certain Melchor de Herrera, paid the Maya Indians working on the cathedral at the rate of 100 cacao beans to the real, whereas he had bought the cacao at a much cheaper rate. If the charge was true, Quijada certainly profiteered, for at 100 beans to the real, a load would have been valued at 30 pesos. This charge referred to the year 1562, at which time the price of cacao was probably less than the 18 pesos per load mentioned below as the price at which cacao had been stabilized for some time prior to 1576. From this same source we learn that Indians bringing provisions to Merida were paid only 20 cacao beans a trip in 1553, a price considerably below the laborer's daily pay of 8–11 *maravedis* (a maravedi was 1/34 of a real, approximately the value given it in *Iolanthe*) The Quijada papers also tell us that the wives of Yucatecan Maya condemned for relapses into paganism were themselves fined sums of 30, 40, or 50 cacao beans for having been in communication with their husbands, an early example of guilt by association.

From the *Relation de Soconusco* (Ponce de Leon 1882) we learn that by 1574 the value of a load had risen to 20–22 pesos, and that figure seems to represent the price in Mexico City. Production then in Soconusco had fallen to only 4000 loads, and another 1000 loads passed through en route from Guatemala to Mexico City. Ponce de Leon noted that the total Indian population had dropped to 1800, and he suggested bringing Indians from other parts to increase production. This decrease in the crop came at a time when demand was increasing. Garcia de Palacio (1860:37, 39), whose letter to the Spanish monarch is dated 1576, commenting on cacao production in Izalcos, western El Salvador, and apparently referring to prices at the plantations, notes that 200 beans were worth a real, and a load was worth 10 gold pesos, or slightly over 15 ordinary silver pesos.

Because of easy transportation by water from Tabasco to Yucatan, a survival of a pre-Colombian trade route, cacao prices in Merida were somewhat lower than in Mexico City. Miss Eleanor Adams has kindly placed at my disposal unpublished material on this subject. From two petitions of Francisco Palomino, Defender of the Indians in Yucatan (Archivo

General de Indias, Mexico, 103 and 101), we learn that a load of cacao in Merida was valued at 18 pesos in 1576, and that that had been its price for a long time past, but by 1579 the price had risen to about 20 pesos.

Sudrez de Peralta (1878, Ch. 24), who completed his book in Spain in 1589, but was describing conditions of a few years earlier, says that a load of cacao brought 28–30 pesos in Mexico City, and 80–100 beans were worth a real. However, a load of the highly esteemed Guatemalan cacao fetched 3 or 4 pesos more, whereas a load from Colima or Huatulco was quoted at less than the standard price. Of about the same time is a statement that in Jalisco 100 beans were valued at a real (Herrera 1728, Dec. 4, Bk. 9, Ch. 13). At that rate the load was worth 30 pesos.

The anonymous chronicler of Father Ponce (Ponce 1875:1:296) puts the cost of a load around 1588 at 30 *reales de á cuatro* on the south coast of Guatemala, but at least 50 *reales de á cuatro* in Mexico City. The *real de á cuatro* is not a real, but a peso of 4 reales, that is to say one worth half the regular peso. Quotations of 15 ordinary silver pesos on the plantation and of at least 25 ordinary pesos in Mexico City are in agreement with the rise in prices observable in the Suarez de Peralta figures.

Torquemada (1723, Bk. 14, Ch. 42), writing in the first decade of the seventeenth century, supplies us with the information that at the time of the conquest a load at the plantation was worth only 4–5 pesos, and in Mexico City only 10–12 pesos, but later it had risen to 15 pesos at the center of production and to 25–30 pesos in Mexico City. He stated that at the time at which he wrote the price in Mexico City never fell below 50 pesos and sometimes rose above 60. He noted that this steep rise reflected supply and demand: there had been a great decrease in population and consequent fall in production in the cacao-growing districts, but consumption had grown with the popularity of the beverage among the Spaniards of Mexico, and the heavy demand in Spain was a factor.

Vasquez de Espinosa (1942, §642), writing apparently of conditions in 1621, puts the price at the source of supply in southern Guatemala at 200 beans for a real or less. A further statement that a load was worth at least 10 ducats agrees with this; the ducat was 11 reales, which gives a price of just under 14 pesos a load. The Mexico City price may have been about 25 pesos. This considerable drop from Torquemada's closing price is supported by Thomas Gage's statement indicating that when he was in Mexico (1625) the price was 22–25 pesos a load. As demand can hardly have fallen enough to cause such a marked recession in price since Torque-

mada wrote, it is perhaps best to assume that a sharp decrease in production at the turn of the sixteenth century, presumably due to disease among the trees or those that tended them, caused a temporary rise in prices. It was of short duration, and brought other producers, Venezuela and perhaps Ecuador, into the field. Vasquez de Espinoza (1942, §272) gives 1615 as the start of Venezuela as a large-scale producer of cacao. This competition may have deprived Mexico of her Spanish market, and thus led to overproduction and falling prices.

Miss Eleanor Adams has kindly supplied me with an important entry for the mid-eighteenth century, which, as she notes, discloses a marked recession in price. The entry refers to a sale in 1753 of 150.5 loads from the provinces, of 60 pounds' each, which sold at 12 pesos a load, as well as some which sold at 10 pesos, "these being the current prices for the said fruit at those times" (Archivo General de la Nación, Mexico, Civil, 753).

Humboldt (*fide* Garcia Payon and Monreal y Jimenez Embun 1936) reports that in his time 80 beans were worth a real, which would have been 37.5 pesos a load, not much different from prices over 250 years earlier, but a big rise from the mid-eighteenth century price just quoted. For the last decades of the nineteenth century, when cacao was ceasing to be a currency, we have the statements of Stoll (1886:103) that 16 beans were worth a *cuartillo*, which gives a rate of 64 beans to the real, and of Habel (1878:4) that 100 beans were valued at a real, then worth 3 American cents, but these were retail prices for small transactions in Indian markets; reckoning wholesale cacao by xiquipil must long have ceased.

With regard to purchasing value, Oviedo y Valdés (1851–1855, Bk. 8, Ch. 30) informs us that in Nicaragua a slave cost approximately 100 beans (one suspects a mistake here) a rabbit was worth 10 beans, the hire of a prostitute was 6–10 beans, and a *munonzapote* fruit was valued at half a bean. From Motolina (1914, Trat. 3, Ch. 8) we have the important statement that the daily pay of a *cargador* was 100 beans.

Sahagun (1938, Bk. 10, Ch. 18) has left an interesting account of cacao merchants which I give below in rather free translation:

"The dealer in cacao generally has inherited properties of cacao and has large supplies which he takes long distances to sell, or he buys to sell retail. A good dealer in this merchandise sells beans which are all picked over for size and weight, and he keeps the grades apart, in one lot those which are of best quality in size and weight, and in another those which are of

little value, not well filled out or broken, and he keeps the remainder also in a separate lot. He also separates the different varieties, namely those from Tochtepee, those from Anahuac, those from Guatemala, those from Guatulco, and those from the Xolotec country. He also keeps separate those that are whitish, ash-colored, or reddish-brown."

"The bad merchant sells falsified beans, for he cooks them and even toasts them to make them look all right, and sometimes puts them in water to make them swell, and he makes them counterfeit the ash-colored or dark beans, which are the best. A trick he has is to toast the poor and almost worthless ones in hot ash and then cover them with clay or damp earth so that they look new and well filled. Another way he has of cheating is to insert within the skin of the bean a blackish dough or black wax which resembles the soft interior of the bean, and sometimes he breaks avocado rind into pieces and cuts these into round shapes which he inserts under the empty skins of the beans. Those which are small or almost worthless he mixes in with the ash-colored and new beans. He even does the same with the other pseudo-cacao beans or those called *quauhpotlaxtli* [patlaxtli], and all these tricks he plays to deceive the customer."

These falsifications must have been highly ingenious, for samples of them were sent by the Viceroy Mendoza to the Spanish court (Icaza 1928:171), although it is possible that the viceroy merely wished to emphasize that counterfeiting was not confined to coinage of the realm. Cacao was falsified also in Nicaragua; Oviedo y Valdés (1851–1855, Bk. 8, Ch. 30) describes the process in which earth was substituted for the meat of the bean, and the outer skin of the bean so carefully rearranged that the fakes could be detected only by feeling the beans one by one with the finger. The existence of an Otomi term for falsified cacao beans shows that the practice was widespread.

REPRESENTATIONS OF CACAO IN ARCHAEOLOGY

Archaeological material bearing on cacao is rare. A stone jar at Copan carries in relief sculptured objects that seem to represent cacao pods. On Monument 4, El Baul (Thompson 1948, Fig. 5a), the most important Pipil city and a former center of cacao cultivation, one of the sacrificial victims is in jaguar guise and has what seem to be nine cacao pods attached to his arms, legs, and tail. One is reminded of the necklaces of cacao beans worn by the sacrificial victims in rites of the Pipil of Nicarao (Garcia de Palacio 1860:74).

Monument 21 at nearby Santa Lucia Cotzumalhuapa (Thompson 1948, Fig. 6d) carries another sacrificial carving. The scene is wreathed in a vinelike plant, to which are attached similar pods. The markings speak for cacao pods, but the tendrilly stalks have little resemblance to trunks of cacao trees. Cacao seems to have a connection with human sacrifice apart from what these monuments would appear to indicate. In the song to Otontecutli recorded by Sahagun there is a reference to the cacao pod which led Seler (1902–1923:2:1043) to conclude that, like the tuna fruit, the cacao pod was a ritualistic term for the human heart torn out in sacrifice. This ritualistic term might have arisen because of the vague resemblance in shape between the two objects, but more probably because both were the repositories of precious liquids, blood and chocolate. This assumption is fully confirmed by a passage in the series of riddles in the Chilam Balam of Chumayel, for, in one of those tests that only a true chief could pass, chocolate is the symbolic term for blood (Roys 1933:128).

A magnificent sculptured panel at El Tenn, in northern Veracruz, a former region of cacao production, has as its background a tree with oval attachments growing from its trunk and branches. Garcia Payon (1936), who illustrates the piece, was, I believe, the first to identify it as a cacao tree laden with pods. The tree of the south in Codex Fejervary-Mayer has been recognized as a cacao because of the pods on its trunk (Seler 1901:13), and one of the world-direction trees carved on the Temple of the Wall Panels, Chichen Itza (Ruppert 1931, Pl. 11b), may also be a cacao plant, for there is a group of four pod-shaped elements attached to its trunk. The conclusion that one of the world-direction trees could be the cacao finds some support in the mention of *balamte*, *Theobroma bicolor* or patlaxtli together with the jaguar, in the period of darkness before the creation of light and the setting up of the world-directional trees as recorded in the Chilam Balam of Chumayel (Roys 1933:111). Caso (1942) believes that the cacao tree is identifiable on the Teotihuacan mural representing Tlalocan, the paradise of the rain gods.

To conclude the archaeological evidence, we may note that a pottery vessel from Cotaxtla, Veracruz, shaped like a cacao pod attests to the importance of cacao in that region (Melgarejo 1943, unnumbered plate at end). Shook informs me that a second pottery vessel in the form of a cacao pod, which is said to have been found at Iximche, Guatemala, is in the collection of Father Celso Narciso Teletor. Kidder (1943:89o, q) illustrates two pottery vessels with pods, which he believes to be of cacao, in relief. They come from Texcuaco, Escuintla, deep in the cacao zone of the Pacific coast of Guatemala.

RITUALISTIC IMPORTANCE OF CACAO

Cacao was, and still is, of considerable ceremonial importance in Middle America. Landa (1941:164) briefly describes a festival held in the month Muan by those who owned cacao plantations, although this may have been a festival within the 260-day almanac (9 Manik or 8 Cauac?) which happened to fall in the month Muan the year Landa recorded his calendar. As little cacao was produced in Yucatan, and that largely or entirely in dry cenotes, where only a few trees could be grown, one wonders whether he had in mind ceremonies in the eastern part of the peninsula, particularly in the province of Chetumal, where conditions were more favorable. However, Landa's use of the term *heredad*, 'parcel of fertile land,' for the scene of the ceremony, surely the cacao grove, perhaps points to a ceremony in a dry cenote.

At the ceremony each official who took part received a cacao pod, a somewhat trivial gift. A dog with cacao-colored markings was sacrificed, and blue iguanas and other game, as well as plumes and copal, were offered to the deities most directly interested. These were the Chacs and Hobnil, general gods of rain and fertility, whose co-operation was, of course, essential, and Ek Chuah. The last was the god of the cacao, and because he had in his keeping the universal currency of Middle America, he was worshipped also by the merchants. God M of the Maya codices has been identified as Ek Chuah, an identification which is open to question (Thompson 1950:76-77), Ikchaua, surely the same as Ek Chuah, was one of the five principal gods of the Acalan Chontal (Scholes and Roys 1948:57) who were very active in commerce and also growers of cacao, and Chua, who may be the same deity, is named as a leading god of the Lacandon Chol (Tozzer 1913).

There is no evidence that Yacatecutli, god of Aztec merchants, had any connection with cacao, but that the merchants recognized the importance of cacao in their lives is shown by the gifts offered to guests at a banquet given by a merchant returning from foreign parts. Each guest received 200 cacao beans, 100 grains of *teonacaztli* (a highly aromatic yellow flower often ground up with cacao), a sort of spoon of tortoise shell to mix the cacao, and one or two calabashes, presumably to hold the cacao (Sahagun 1938, Bk. 9, Ch. 6).

No information on gods of cacao has survived elsewhere except among the Nicaraos, who raised large quantities of cacao. According to Oviedo y Valds (1851-1855, Bk. 42, Ch. 11) they performed the volador ceremony in honor of Cacaguat, the god of cacao, and an image of him was placed on the platform on top of the pole. Elsewhere the volador cer-

emony does not seem to be associated with cacao, and nothing more is known of this Nicaraean personification of the cacao crop.

An important ritualistic association of cacao which also bears on the question of the directional trees already discussed is found in the lists of the aspects of the 20 Maya days as given in the books of Chilam Balam of Kaua and Mani (Barrera Vasquez 1943). The "tree" of the days Manik and Cauac is said to be "the cacao, the true cacao." The least reliable list has *cacao che* instead of *cacau u che*, possibly changing the meaning, for *cacauche* is a different plant. Nevertheless, there can be no serious doubt that it was cacao which was the "tree" of those two days. The significance of associations with these two days is not clear. Manik, apparently a day connected with hunting, is under the protection of the god of number eleven, an earth deity who has the Caban sign on his cheek; Cauac is closely connected with storms and deities of rain. It is dust possible, though improbable, that Ek Chuah, the god of cacao, is connected with the day Manik (Thompson 1950:76).

Turning from theocratic concepts to everyday ritual, we may note that the present-day Bachajon Tzeltal use cacao beans, gourds, and pine branches to decorate their altars (Blom and La Farge 1926-1927:363). Cacao is frequently offered by the present-day Lacandon to their gods; commonly it is mixed with posole or even with balche (Tozzer 1907:102-103). Their predecessors, the Lacandon Chol, gave animal fat and ground cacao to their idols to eat, putting the latter on the mouth of the idol (Tozzer 1913:505). Cacao or cacao flowers were offered in Aztec ceremonies (Sahagun 1938, Bk. 2, Ch. 35; Bk. 4, Ch. 21), but not with the frequency found in Maya rites, presumably because cacao was not a native plant. The Zapotec still make offerings of cacao, usually together with bread, to crosses, and cacao is offered in sorcery rites (Parsons 1936:121, 301, 452). The Mopan Maya offer cacao in rituals for successful fishing (Thompson 1930:90), and the Mam hierarchy drink it ceremonially as they eat sacrificial turkeys (Oakes 1951:228). Icaza (1928:71) notes that the bell ringers of Mexico City cathedral had a statue of Christ called *El señor del cacao*. It was placed in the portico of the cathedral, and, beside it, baskets to receive offerings from the poor of cacao beans, which were exchanged for candles.

The ceremonial presentation of cacao to village officers when they take office and the handing down of cacao beans from one incumbent to his successor are prominent in Mam ceremonies (Wagley 1949:90, 93, 94). Oakes (1951:63) describes how Mam *rezadores* for the incoming year formally signify acceptance of their post by taking a ball of maize dough, cacao,

and sugar, which has been censed with copal, and placing it in hot water to make the ceremonial drink of chocolate called *bebida*. At the Mam town of Todos Santos, Miss Susan Miles tells me, cacao is served to the prayer makers every 20 days on the return of the year-bearer day name. It is always drunk from decorated gourds, never from European cups, at this and all other ceremonies.

Cacao is rather widely associated with the crises of birth, marriage, and death. At Todos Santos, again according to Miss Miles, it is served at the little feast held on the 20th day after a baby's birth. Among the present-day Chorti of Quezaltepeque a mother customarily sends gifts of bread and cacao to the godparents before and immediately after the birth of the child, and also after its baptism (Wisdom 1940:292). Among the Pipil, cacao, birds, and copal were offered when a child was named, 12 days after birth (García de Palacio 1860:81). In prequest Yucatan, children at a puberty rite were anointed with virgin water in which flowers and powdered cacao had been mixed (Tozzer 1941:105). In present-day Yucatan, bread, cacao, and rum are ceremonially consumed on the very important occasion of a man's consenting to act as godfather (Redfield and Villa Rojas 1934:193). Exchange of presents of cacao, bread, and accessories when a marriage is being negotiated is also a Yucatec custom (Redfield and Villa Rojas 1934:189). That this is an ancient rite is shown by the expression *tac haa*, roughly translatable as 'serve chocolate,' which the Motul dictionary translates as 'to invite the father of a girl whom one's son wants to marry to discuss the marriage and serve him drink.' Clearly, the cacao was of paramount importance in this ceremonial opening gambit. Among the Lacandon Chol, groom and bride exchanged presents; he gave her skirts and 5 cacao beans, whereas she gave him a stool and 5 cacao beans (Tozzer 1913:507). Herrera (1728, Dec. 3, Bk. 7, Ch. 5) writes of an unspecified group in Honduras that in concerting a marriage the go-between presented 160 cacao beans to the family of the girl on the first visit and a similar amount the following day. The offering consisted of 4 *tucas* of beans, and Herrera tells us that a *tuca* comprised 40 beans. *Tuc* is a Maya word for 40 used by the Kekchi, Pokomchi, and Quiché. The use of *tuca* in this passage would indicate that the group in question was Maya, presumably Chorti or, just possibly, Pokoman.

Among the Mam of western Guatemala it is customary to make a gift of a spray of wild flowers, 4 reales, and 4 cacao beans to the parents of a girl whose hand is being requested in marriage (Wagley 1949:129). Here, as among the Lacandon Chol, the cacao beans might be a survival from the days when

a token payment in cacao currency was made. Atole de cacao plays an important part in marriages at Mitla (Parsons 1936:105, 456). The offering of cacao and maize or bread to the dead occurs among the Zapotec (Parsons 1936:281, 381) and among the Maya of Yucatan (Redfield and Villa Tojas 1934:152). Page 67 of the Mexican Codex Magliabecchi (1903) illustrates the preparation of the dead, and the text declares that the deceased was supplied with cacao for his journey to the next world. Page 72 of the same codex shows an offering of cacao in a pedestal vase made to the dead in their feast in the month Tititl.

These citations bring out the rather general association of cacao with maize and perhaps, more recently, with wheat bread. This combination surely derives from pre-Columbian practice; at least, we find that, in a sacrificial rite performed in Yucatan only two decades after the conquest, the foods offered comprised deer cooked *chirimole* style, three heads of deer, much bread, that is maize, and cacao in *posole* (Scholes and Adams 1938:1:139).

MEDICINAL PROPERTIES OF CACAO

Medical properties have been assigned to cacao at various times. The Chontalapa of Oztoman used the bark of the tree as a cure for bloody stools (*Papeles de Nueva España*, 1905, ser. 2, vol. 6, p. 111); in Yucatan it was prescribed for abdominal pains and for poisoning (Roys 1931:222); the Badianus Aztec herbal recommends cacao flowers as one of the ingredients for potions to remedy such diversity of illnesses as cuts on the feet, mental apathy, and marked timidity (Badiano and de la Cruz 1939:65, 97, 98). In Nicaragua cacao fat was used as a disinfectant on cuts, and Oviedo y Valdés (1851–1855, Bk. 8, Ch. 30) bears personal witness to its efficacy. Cacao was also regarded by the Indians of Nicaragua as a sovereign remedy against snake bite and any kind of poison, and it was believed that a person who had drunk cacao in the morning would not die if bitten by a poisonous snake that day.

According to Fuentes y Guzmán (1932–1933:2, Bk. 2, Ch. 7), doctors in Guatemala prescribed application of cacao fat for burns and for the liver and lungs. We are not told whether these remedies were taken over from the Indians or were post-Colombian discoveries.

Oviedo y Valdés in the passage cited describes a peculiar custom of the Indians of Nicaragua. Both men and women smeared chocolate paste, either plain or mixed with annatto, over their faces, and they regarded this as a way of enhancing their good looks. From time to time they rubbed a finger on this

mixture smeared on their faces and licked it, thereby assuaging their hunger. Gage (1677) mentions that Mestizas, apparently in Chiapas, used cacao fat on their faces.

Garcia de Palacio (1860:37) reports that the Pipil of Izalco, El Salvador, performed libidinous rites including sexual intercourse when they planted cacao seed. The planting was at full moon, and the best seed was first exposed for four nights to the night dew.

In some parts cacao could be drunk only by those of high rank. The common people of Cuicatlan, Oaxaca, were not allowed to drink cacao (*Papeles de Nueva Espana* 1905:4:186); in Nicaragua, according to Oviedo y Valdes (1851–1855) only the powerful people drank it; poor people either did not dare to drink it or could not afford thus to consume wealth.

There is an inferior variety of cacao called patlaxtli or patlachtli. It was given as alms to the poor (Icaza 1928:7). Fuentes y Guzman (1932–1933:2, Bk. 2, Ch. 7) says that it was liked by the Indians, but that the Ladinos found it harmful. From the south coast of Guatemala it was shipped to Yucatan. Wisdom (1940:292) remarks that it is not much liked by the Chorti and Torquemada (1723, Bk. 14, Ch. 42) says that it was mixed with regular cacao, adding that it caused headaches. Patlaxtli is *Theobroma bicolor*, which grows wild throughout the Maya lowlands.

Names for patlaxtli in several Maya languages mean jaguar or jaguar tree; it is tempting to see a connection here with the jaguar apparently decked with cacao pods on the relief at El Baul already mentioned.

PREPARATION OF CHOCOLATE

Within the space of this paper it is impossible to enter into all the ways in which chocolate was served. The commonest recipe in most parts of Middle America called for cacao, ground maize, and annatto. Cacao and annatto figure in the interrogation of the chiefs in the Chilam Balam of Chumayel (Roys 1933:95–96). Chile is a frequent ingredient; the Mopan Maya of San Antonio, British Honduras, have substituted the black pepper of the Old World for chile, and serve this with cacao and ground maize, a truly foul mixture. The many recipes for the serving of chocolate are to be found in various entries listed in the references at the end of this paper, notably in the book of Archbishop Leon Pinelo (1636), who gives 120 recipes. Popenoe (1919) enlivened the pages of the *American Anthropologist* with others. Garcia Payon (1936) delightfully covers the social aspects of chocolate drinking in all ages.

ORIGIN OF THE WORD CACAO

The origins of the words cacao and chocolate are not easily found. There has been a considerable amount of speculation on the subject, but it is to be doubted that any conclusion satisfactory to everyone will ever be reached. Both words certainly derive immediately from Nahuatl, but Nahuatl-speaking peoples probably borrowed in turn from some other language, for Nahuatl-speaking peoples penetrated to cacao-growing areas presumably long after the plant had been brought under cultivation, and then in relatively small numbers.

It has been suggested that the Yucatec use of the term *cacao* is a post-Colombian borrowing from Nahuatl, but there are arguments against this theory. The word *cacao*, with slight variations in pronunciation and spelling, occurs in the following Maya languages or dialects: Yucatec, Mopan, Palencano Chol, Manche Chol, Chorti, Chontal, Tzeltal, Tzotzil, Chanabal, Pokomchi, Kekchi, Quiché, and Cakchiquel. One may safely assume that the term occurs in all or nearly all the remaining Maya languages or dialects, but I have not been able to verify the assumption. In the case of Chontal there is evidence that the term *cacao* was in use in the sixteenth century, and probably much earlier, for, with the locative *tah* before it, the word appears as the name of a Chontal village in Document II of the Paxbolon-Maldonado papers, which is a copy of an original probably drawn up in 1567 (Scholes and Roys 1948:362). Furthermore, in Mopan and Palencano Chol the term is *cucu* and *cucuo*, respectively, these two forms reflecting the shift from an a to a u sound like the a in nurse. From this we can conclude that the word *cacao* was in common usage in those two tongues before the sound shift, of uncertain date, took place. Again, the occurrence of the word *cacau'* as a Chorti family name (Wisdom 1940:252) suggests that that group had a long acquaintance with the term, although a few Chorti names are post-Colombian.

In contrast to the apparently uniform distribution of the term *cacao* throughout the Maya area (it occurs also in the variants form *cacaua* among the Zoque, who are neighbors of the great growers and traders of cacao, the Chontal Maya), most non-Maya and non-Nahuatl-speaking peoples have terms for cacao which are completely unrelated to the Maya *caco* or *cacao* or to the Nahuatl *cacauatl*. A cursory examination of vocabularies shows that observation to be true of Zapotec, Mixtec, Matlatzinca, Otomi, Mazahua, Tarascan, Chiapanec, Xinca, Paya, and Mangue. Not only are the terms in those languages unrelated to cacao; they are also distinct from one another.

As the neighbors of the Aztec, who live for the most part in territories unsuited to the production of cacao, did not use for this alien product terms related to the Nahuatl *cacauatl*, it seems highly unlikely that the distant Maya, who do live in a cacao-producing country, would have discarded their own name or names for the tree in favor of one derived from the Nahuatl. Conceivably, this could have happened in one or two Maya linguistic groups, but certainly not in no less than thirteen Maya languages or dialects, all about which I have been able to gather information. Accordingly, it is surely more reasonable to suppose that the Nahuatl term *cacauatl* derives from the Maya *cacau* rather than the reverse. Possibly the term originated among some other group in the cacao-producing area. As we have noted, the Zoque use the term *cacaua*, but Zoque territory by and large is not cacao-producing.

For chocolate there is no general Maya term. The Yucatec term was *chacau haa*. *Chacau* means hot; *haa*, apparently with a strong h, may have no connection with *haa* or *ha*, 'water,' the h of which is not *recia*, although the difference between simple and strong h must have been slight, for it is now lost. As chocolate was drunk cold, and as *chacau haa* was also used for solid chocolate, the term probably refers neither to hot nor to water. In that connection it may be of significance that the word *haa* occurs in the Quiché term for cocoa butter, *vuihaa*. It is tempting to suppose that *chacau* is the lowland equivalent of highland Maya *cacau*, just as lowland *chac*, 'red,' pairs with highland *cac*. Were that assumption to be validated, it would be evidence that cacao was first cultivated on the Pacific slopes of the Guatemalan highlands, but one would have to explain why the shift appears only in the Yucatec name for chocolate, while the commercial bean continued to be known everywhere as *cacao*. Needless to say, such reasonings are highly speculative.

CACAO'S PART IN CULTURAL DEVELOPMENT

Cacao certainly stimulated trade throughout Middle America and, with trade, the spread of ideas; it may have been partly responsible for the great development of arithmetic and, concomitantly, the growth of that whole framework of time that distinguishes the Maya from all other civilizations. The Maya never learned to measure by weight, and, although measures of capacity were undoubtedly used in large transactions, they served merely to facilitate business deals, they did not supplant the ancient system

of reckoning which had as its unit the single bean. Such transactions surely accustomed the Maya and their neighbors to handle large numbers and perhaps paved the way for the Long Count and later developments in that wide field comprised in the philosophy of time.

If we be permitted to carry this speculation a step further, we should perhaps seek the beginnings of lengthy time calculations, such as the Initial Series, in an area suitable to cacao plantations, namely the belt stretching from the north coast of Honduras westward to central Veracruz, and the lowland strip on the Pacific coast of El Salvador, Guatemala, and Tehuantepec. It may be no more than coincidence that the highlands of Anahuac and of Guatemala, which are unsuited to cacao cultivation, have no Long Count texts, whereas the cacao-producing areas have yielded most of the very early calendrical inscriptions that appear to have progressed beyond the Calendar Round.

ADDENDUM

Ruth Bunzel (1952:25, 44, 113–15, 239–242) emphasizes the importance of cacao in many ritual patterns, but particularly in the ceremonies of requesting a girl in marriage. The petitioners ask for a table for the gift of 25 or 30 cacao beans, and if that is refused, negotiations are at an end. The first gift contains, in addition to the cacao beans, *sapuyul*, a condiment used in the preparation of the cacao drink. Acceptance of this gift indicates the willingness of the girl's family to consider favorably the petition. Other food gifts, together with more cacao beans, are made on subsequent visits. These include atole made with toasted cacao. The expression "bread and chocolate" is used.

Cacao, says Bunzel, is the taboo tree (Spanish *pecado arbol*; Quiché *ahuas che*). It is said that when Christ was pursued by His enemies, He took refuge under a cacao tree, and the tree let fall a blanket of blossoms to hide Him. Christ blessed the tree and decreed that it should never be used for firewood and that its beans should be on the table at all ceremonies, "... whenever my children's children take wives and husbands, they will see you upon the table," and "... you shall always be there to remind them of my sufferings in all the holy ceremonies."

In some ceremonies, such as that of the commemoration of the dead, offerings of coins are now made. It is possible that these have replaced cacao beans in this region which produces no cacao.

Tohil Plumbate and Classic Maya Polychrome Vessels in the Marquez Collection

Robert E. Smith

This collection, located in Merida, Yucatan, Mexico, belonged to the late Alberto Márquez, a collector for twenty-five years. It consists for the most part of Maya archaeological material. At present there is a preponderance of ancient Maya and Mexican pottery, including several thousand Jaina figurines both modeled and moldmade, some 200 X Fine Orange vessels, about 100 fine gray specimens, over 50 Tohil Plumbate pieces, a dozen or more Classic Peten-like Polychrome examples, and some miscellaneous ceramic types. This note has to do with 53 Tohil Plumbate and 12 Classic Peten-like Polychrome vessels.

The exact provenience of the specimens is uncertain. In all probability the great majority came from somewhere along the coast of Campeche, from such sites as Jaina, Huaymil, Isla de Piedra, Campeche, Champoton, and even Isla del Carmen. Since nearly all the objects are whole, they presumably came from tombs or caches. In no instance, however, is the complete contents of a grave known, nor is it even certain that any two vessels were found together. The associations of these valuable finds are lost forever. Today the value of such collections is simply typology; large groups of the same ware or type can be analyzed, and the variety of shapes, techniques of decoration, and styles of design within those groups can be recorded.

TOHIL PLUMBATE VESSELS

Plumbate, a ware with a hard lustrous surface attributable principally to the use of a fine-textured clay

of high iron content and to a reducing atmosphere at temperatures around 950° C. (Shepard 1948:99), may be separated into three main types. The earliest of these is San Juan Plumbate (Shepard 1948:91), possessing a distinctive paste and made up of simple shapes such as the cylindrical vase and the squat, collared jar with little decoration. The most recent type is Tohil Plumbate, thoroughly described and illustrated by Shepard and composed of effigies, jars, tapered vases, barrel-shaped vessels, and bowls, most of them well decorated. A third type, Robles Plumbate, may be placed chronologically between San Juan and Tohil. It is less well known than the other two, and is notable in that much of the design is moldmade (Shepard 1948, Fig. 12n).

In this assemblage of 53 plumbate vessels from the Marquez collection we deal only with the Tohil type. Shepard's valuable plumbate study gives illustrations of all the forms in this collection except two: a double body-bulge jar (Fig. 129.2l) and a recurved-sided tripod jar (Fig. 129.1g), Shepard also reproduces all the decorative techniques found in this group of vessels: grooving; incising and punctuation; modeling, including all effigies; and gadrooning. The last process is described as follows: "The elevation of parts of a surface to produce ribs, lobes or bosses is a common plumbate decorative technique used on bodies of jars and pyriform vases, on bulging necks of jars, and on barrels. The effect is produced by pressing out the vessel wall, or by deep grooving usually combined with modeling and slicing or trimming" (Shepard 1948:17). Shepard also

illustrates all the design motifs found in this collection. All the styles of design recorded here are abstract, including scroll meander, simple scrolls and related elements, rectilinear and simple curvilinear, reverse curve, elaborate scroll bands, and the loop and scroll motifs.

CLASSIC MAYA POLYCHROME VESSELS

The 13 vessels of this type included in the collection are all Classic Maya Polychrome gloss ware (Smith 1955) save one specimen of Classic Maya Dichrome gloss ware (Fig. 129.7d). The exact period or phase to which each example belongs, however, is not always clear. Some have a design style of one phase and the form of another (Fig. 129.6b), or the design style of one period and the form usually belonging to a different period (Fig. 129.7b). Most of the tripod vessels have forms unusual or unknown at such sites as Uaxactun, Piedras Negras, or San Jose; yet most of the associated design styles are typical of those places. Apparently, design style was diffused more widely than vessel shape, and many of these non-Peten-like forms may have originated somewhere in Campeche but with design styles representative of the Peten.

Fig. 129.1. Tohil Plumbate (a–g) and Classic Peten-like Polychrome (h–j) Vessels.

a. Jar, griddle shoulder tripod with rim molding and medial molding; gray with few orange spots.

b. Pyriform pedestal-based vessel with horizontal rim, basal grooves and a grooved band of semi-circles, oblique lines and short pendant lines framed by horizontal grooved lines; orange and dark gray. See Figure 129.3b.

c. Pyriform pedestal-based vessel with rim and medial moldings (made from interior by pushing out); rim ovoid in plan; gray and cinnamon color.

d. Pyriform pedestal-based vessel with rim molding and grooved band of elaborate scrolls and related elements; mottled orange and gray. See Figure 129.3f.

e. Pyriform tripod with wall-base angle and decorated with a grooved *ilhuitl* sign band framed by moldings and horizontal grooves; orange with dark spots. See Figure 129.3j.

f. Pyriform tripod with wall-base angle and decorated with rim molding and two grooved bands, the upper of semicircles, vertical lines, and short pendant lines, the lower of a scroll meander; red and a few gray spots.

g. Recurved-sided tripod jar with two grooved bands, the upper of step-frets, the lower of hand bells and hooks; dark gray to almost black.

h. Tripod basal-flange bowl with solid conical feet; red-and black-on-orange; slipped and burnished all over save base; interior black semi-disk rim band, exterior decorated with upper glyph-like band of repeated heads and lower band of terraces. Tepeu 1 design, but shape unusual. See Figure 129.7a.

i. Tripod, wide-everted rim dish with hollow conical feet; orange-and-black-on-buff decoration on interior only with glyphlike rim band and human figures with corn (?) plants shown on floor; feet have circular side vent. Tepeu 2 (?) type. See Fig. 129.6e.

j. Tripod basal ridge wide-everted rim plate with hollow conical feet; red-and-black-on-orange decoration on interior only with glyphlike rim band and floor design showing two seated human figures and two deer (?), a presentation reminiscent of Ulua-Yojoa Polychrome. See Figure 129.7c

Scale is 1/4.

Fig. 129.2. Tohil Plumbate Jars.

a. Standard jar with slight rim molding and flat base; orange and dark gray evenly distributed; overall ht. 12 cm.

b–d. Standard jars with vertically gadrooned (all worked from exterior) bodies. **B.** slightly concave base; grooved neck band of simple scrolls and related elements; red and some gray; overall ht. 17.5 cm. **c.** concave base; mottled gray and orange; overall ht. 14 cm. **d.** flat base; orange, brown, and dark gray; overall ht. 16.6 cm.

e–g. Bulging-neck tripod jars with hollow oven-shaped feet. **E.** gray and orange; overall ht. 15 cm, brown with gray areas; overall ht. 17.1 cm. **g.** orange with gray patches; overall ht. 14.6 cm.

h. Bulging-neck pedestal-based jar; drab gray and light brown; overall ht. 12.7 cm.

i. Griddle shoulder jar with concave base; neck and body grooving; gray with orange edging; overall ht. 17.7 cm.

j. Standard tripod jar with hollow oven-shaped feet; decorated at body-neck junction with three lateral ridges; red with black fire-clouded areas; overall ht. 17.2 cm.

k. Standard pedestal-based jar with horizontal grooves at neck-body junction and at mid-body; orange neck and body with dark gray areas on body base and pedestal; overall ht. 16 cm.

l. Double body-bulge jar with rim molding and dimple base; red and dark gray or almost black area on one side of body and over most of neck interior; overall ht. 11.5 cm, wall thickness 0.3–0.5 cm.

129.2. Tohil Plumbate jars.

Fig. 129.3. Tohil Plumbate Pyriform Vessels.

a–h. Pyriform pedestal-based vessels, a, horizontal grooving and widely spaced petal-shaped gadroons; gray with copper tints; overall ht. 17.6 cm; b. see Figure 129.1b. c. grooved elaborate scroll band framed by lateral moldings; mostly orange and some gray; overall ht. 21.3 cm; d. grooved elaborate scroll band framed by lateral moldings, gadrooned lower body, and potter's mark on base (Shepard 1948, Fig. 9, fourth from left); drab and gray; overall ht. 21.3 cm; e. two sets of three horizontal grooves above gadrooned lower body; orange and drab; overall ht. 18.3 cm; f. see Figure 129.1d; g. grooved band of simple scrolls and related elements; orange and green-gray; overall ht. 20.6 cm; h. rim molding and upper body gadroon above grooved scroll meander framed by horizontal grooving and gadrooned (worked from exterior) lower body; pedestal has grooved scroll meander; dark gray with orange edging; overall ht. 21.4 cm.

i–l. Pyriform tripods with hollow oven-shaped feet; i. grooved band of simple scrolls and related elements framed by lateral moldings; orange plus gray areas; overall ht. 18.7 cm; j. see Figure 1.29e; k. two sets of three grooves (may be chamfered; greenish copper color; overall ht. 19.8 cm; l. rim molding and two body moldings; mostly green-gray with orange areas; note crack mending holes (3 sets of 2 each); ovoid orifice with lip diam. 6 by 6.7 cm, overall ht. 15.2 cm.

Fig. 129. 4. Tohil Plumbate Animal and Human Effigy Jars (Styles According to Shepard 1948, Figure 13).

a, b. Style I, head alone; a. human; brownish red with gray to black spots; crazed; concave base; overall ht. 17.5 cm; b. Jaguar and gadrooned (worked from interior) body; red with few black or dark gray areas; concave base; overall ht. 12.8 cm.

c–i. Style III, crouching; c. Jaguar; potter's mark y; concave base; overall ht. 15 cm; d. frog; gray with orange edging concave base; overall ht. 12 cm; e. frog; gray with orange edging; concave base with four frog feet; overall ht. 13 cm; f. Jaguar; rim molding; gray with orange edging; concave base; overall ht. 11.5 cm; g. Jaguar; gray with orange spots and edging; concave base with potter's mark ø; overall ht. 13.8 cm; h. monkey; brown and gray in spots; concave base; overall ht. 14.5 cm; i. pisote; orange with dark gray areas; legs hollow and open at bottom; overall ht. 14.8 cm.

j. Style IV, standing; frog; all gray save orange head and feet; rim molding; overall ht. 7.8 cm.

k, l. Style VIII, standing with forelegs in round; k. Jaguar with human head in mouth; orange and

gray; dimple base; lip broken off; overall ht. 12.5 cm; l. animal with hollow front legs open at bottom and solid slab rear legs; dark gray; neck cut down; overall ht. 13.7 cm.

m, n. Style IXa, realistic body; m. jaguar; gray with orange edging; some crazing; neck cut down; overall ht. 14 cm; n. animal; orange with gray areas; overall ht. 15.7 cm.

Fig. 129.5. Tohil Plumbate Anthropomorphic and Bird Effigies.

a–g. Anthropomorphic styles according to Shepard (1948, Fig. 17); a. Style I, bearded head; rim molding; concave base; gray with reddish areas; overall ht. 10.8 cm; b. Style I, old bearded man; orange plus dark gray areas; overall ht. 15.9 cm; c. Style I, front and side view; rim molding; bronze with dark gray or black areas; overall ht. 17.9 cm; d. Style IVb, entire figure, kneeling; gray; overall ht. 20 cm; e. Style IVb, entire figure, kneeling; reddish brown; concave base; overall ht. 14.9 cm; f. Style IVb, entire figure, kneeling; gray with orange edging; overall ht. 17.2 cm; g. Style IVb, entire figure, kneeling old man with spiked birdlike tail; overall ht. 15.8 cm.

h, i. Bird effigies (Shepard 1948, Fig. 16,k); h. jar; concave base, orange and dark gray; overall ht. 8.5 cm; i. miniature effigy; flat base; rim molding; gray and orange; over all ht. 8.5 cm.

Fig. 129.6. Classic Peten-like Polychrome Tripods.

a. Wide everted-rim tripod plate with three solid oven-shaped feet; red-and-black-on-orange; exterior slipped lightly and burnished, interior both slipped and burnished and decorated with encircling rim band of black hand bells and floral floor design; lip diam. 22.8 cm, wall thickness 0.5–0.7 cm. Tepeu 2 type.

b. Tripod plate with three solid nubbin feet; red-and-black-on-orange; slipped and burnished on interior and exterior down to base and partly on feet; only interior decorated with encircling glyph band of repeated heads and seated human figure as floor motif; lip diam. 26.2 cm, wall thickness 0.7–1.0 cm. Tepeu 2 form and Tepeu 1 design style.

c. Tripod convex-based dish with hollow cylindrical feet open at base; red-and-black-on-orange; exterior lightly slipped and burnished on upper half; interior slipped, burnished, and decorated with encircling band of crosshatched ovoids framing a deerlike figure on floor; mending holes; lip diam. 31 cm, wall thickness 0.5–0.8 cm. Tepeu 1 (?).

d. Tripod flat-based plate with hollow oven-shaped feet; red-and-black-on-orange; exterior lightly slipped and burnished to base, interior slipped, bur-

A New Inscription from the Temple of the Foliated Cross at Palenque

Heinrich Berlin

In Note 120 of this series J.E.S. Thompson stated that a fragmentary text from the Temple of the Sun at Palenque, published by the writer in Note 24 of this same series, fitted another fragment seen by Thompson in the Palenque storeroom. This statement is incorrect. Although the fragment published by Thompson fits the hieroglyphic text published in Note 24, it does not fit the actual fragments of the stone. His reading, however, remains valid.

When I was at Palenque in 1956 I had time to inspect the storeroom. Among the pieces there I noticed many carved stone fragments marked "Temple of the Foliated Cross." On being assembled they turned out to form a complete tablet, a drawing of which is published here (Fig. 130.1) with the kind permission of Sr. Alberto Ruz.

The tablet is composed of fourteen fragments (one small one is not shown separately on the drawing). Six were extracted during the 1953 excavations by Cesar Saenz from a pit inside the sanctuary, where he also found fragments of the large human figure tablets which existed on the façade of the sanctuary on either side of the doorway, together with splinters of glass. Hence it is evident that we are dealing with one or more rather modern excavations later refilled with whatever material was at hand.

Another fragment was found, also by Saenz, in 1954 on the lower temple terraces.

Seven fragments, according to the catalogue, were in the storeroom before 1951. Three of them are catalogued as from the Temple of the Foliated Cross; no provenience is given for the remaining four. As

I do not remember having seen any of these seven fragments during the field seasons from 1940 to 1942, when I was at Palenque, I imagine that they were found between 1943 and 1945 by the late Miguel Angel Fernandez.

The whole tablet measures 173 by 33 by 5 cm. On the narrow edge at the right there is carved a frame (Fig. 130.1); the corresponding left edge is plain. Examination showed the front walls of the sanctuary to be 25.5 cm thick. The new tablet exactly fits the door jamb in height, and the excess width of 7.5 cm corresponds to the thickness of the human figure tablet on the façade. For checking the projection of the façade tablet, we possess at present only fragments of the left (northern) one, which is about 5 cm thick. This tablet further shows a frame decoration 15 cm wide on the left side and 6 cm wide on the right side. Assuming that there were two jamb tablets, then the frames on the narrow edges were carved in order to complete the frames of the human figure tablets. I conclude, therefore, that the tablet under discussion must originally have been set against the right (southern) jamb.

It is strange that not one of the earlier writers on Palenque, who may have seen these jamb tablets *in situ*, mentions them. It is, of course, possible that they had been ripped off in pre-Spanish times. The writer regrets that he did not ascertain the exact location in the debris of the fragments published in Note 24. Incidentally, these were found in 1941 and not in 1942 as stated in that note.

The situation at the Temple of the Sun is similar. The thickness of the sanctuary wall of the temple is

130.1. Tablet from sanctuary in Temple of the Foliated Cross, Palenque.

32 cm, and the width of the fragment published in Note 24 is about 41 cm. Blom and LaFarge (1926–1927:1, Fig. 158) have published another fragment, Blom's Tablet No. 1. This is 39 cm wide and was found behind the Temple of the Sun. Here, then, we appear to have good evidence for the existence of inscribed tablets for both door jambs. It is curious that both of them show the 5 Eb 5 Kayab date.

On the other hand, the sanctuary walls of the Temple of the Cross are 31.5 cm wide. It is just possible that Tablet No. 1 once belonged to the Temple of the Cross. This requires the assumption that Blom's informant gave an incorrect provenience for this piece. Were that the case, then in each of the three temples one of the door jamb tablets would have had the same Calendar Round date. Other fragments, now in the storeroom, found around the Temple of the Cross may eventually supply the solution to this problem.

The reading of the calendaric part of our tablet presents no problem. A1-B4 read 5 Eb, G3F, 5 Kayab, 11D, 3C, X, B, 9A, corresponding to the Long Count 9.12.19.1.12.

The lunar data are exactly the same as those found with the same date on the fragment reported in Note 24. Again, Glyph G3 is recorded instead of Glyph G4, which this date calls for. Unless one assumes that the mistake was carelessly copied from whichever tablet was the earlier, one must suppose that this shift was intentional. It is curious that on both tablets a Calendar Round date, "wrongly" placed in the Long Count by Glyph G, is followed by a complete lunar series, which usually occurs only with Initial Series.

Glyphs A5 to B7 have been read by Thompson in Note 120.

The remaining glyphs, A8-B12, show a distance number in B10 of 3 uinals and 8 kins, a Calendar Round date 8 Ahau 8 Uo in A11b B11a, what is probably the seating of the tun in B11b, and 13 Katuns in A12. Indeed, adding the distance number to 9.12.19.1+.12 we reach 9.13.0.0.0 8 Ahau 8 Uo:

A1-A2	(9.12.19.14.12)	5 Eb 5 Kayab
A5-B5	1.7.11	Subtract
B6-A7	(9.12.18.7.1)	1 Imix 19 Ch'en
B10	3.8	Add to first date
A11-A12	(9)13.(0.0.0)	8 Ahau 8 Uo, seating of the tun

The Marquez Collection of X Fine Orange Polychrome Vessels

Robert E. Smith

Approximately 200 X Fine Orange and fine orange polychrome vessels, the latter in small number, are included in the collection of the late Alberto G. Marquez of Merida, Yucatan, Mexico. The specimens, mostly whole and in excellent state of preservation, are said to have been found for the most part on Isla de Jaina and at Huaymil. The latter site, sometimes called Huaymin, is located 16 km north of Jaina (Shook 1955) on the northern coast of Campeche. Although the provenience of these vessels is by no means certain, there is no doubt about their belonging to, or being associated with, the X Fine Orange and fine orange polychrome categories. The present description of this collection is a contribution to our knowledge of shape, methods of decoration, and styles of design.

WARE

The essential characteristics of X Fine Orange paste are its fine texture, homogeneity, lack of temper, and orange color. The color is always even throughout the section; according to Brainerd (1941), although usually orange, it may occasionally range to gray. Since this collection is composed mostly of whole vessels it was possible to inspect sections of only a comparatively few cracked or slightly broken specimens. In general, the paste color is somewhat lighter than the slip or surface, which may on occasional specimens be well burnished rather than slipped. The most common surface color is 2.5YR5/8 all color readings from Munsell 1929). Other colors noted

(28 specimens examined for colors are, in order of importance, 2.5YR4/8, 2.5YR6/8, 5YR6 /6, 10R4/6. Thirteen specimens have a large darkened (2.5YR4/6 and 10R4/8) lower wall area covering from half to two-thirds of the vessel's exterior. These are confined to six shapes, all shown in Figure 131.1d, a, 1 (two examples); b, 2 (six examples); b, 4 (two examples); c (one example); d, 1 (one example); d, 2 (one example). Three pyriform vessels have blue paint on the inside of the pedestal bases. Two of these blues suggest Maya blue (Fig. 131.8c), and one is purplish blue (Fig. 131.12d).

The fine orange polychromes included in this study are of two varieties: the four-color polychromes (red-black-and-white-on-orange) and the three-color polychromes (red-and-black-on-orange, red-and-white-on-orange, and white-and-black-on-orange). The four-color polychromes appear to have approximately the same surface color range as the X Fine Orange examples. The three-color polychromes differ somewhat in surface color (5YR 5/4, 5YR5/6, and 5YR4/6) from the X Fine Orange range. The reds recorded on all fine orange polychromes examined are 7.5R3/6, 7.5RP3/4, and 2.5YR5/6. The four-color polychromes occur with four shapes (Fig. 131.1b, 5; d, 3, 4; g). The most frequent (Fig. 131.14, h-k) is a common X Fine Orange form; the others (Figs. 131.16c, e; 131.17h) are rare X Fine Orange shapes. The three-color polychromes are for the most part found with forms (Fig. 131.1d, l, 4; e, 3; f) not normally associated with the X Fine Orange type, but the white-and-black-on-orange is used on two com-

mon X Fine Orange shapes (Fig. 131.1b, 5, 7). These last (Fig. 131.14, g, 1) also suggest Cerro Montoso Fine Polychrome.

VESSEL FORM

SHAPE CLASSIFICATION (FIG. 131.1)

Brainerd (1941:164–169) has grouped X Fine Orange form into five main classes: globular jars; pyriform vessels; cylindrical vessels; bowls of several distinctive forms, including flat-bottomed basal-break and round-bottomed basal-break graters; tripods, hemispheroid and taper lip bowls; and rare and elaborate forms. In the Marquez collection the same main classes, with certain additions and new variations are present:

a. Jars, the standard form having a globular body with angle at body-neck juncture, usually a concave base, and (1) with outcurving or (2) with flaring neck. Other modifications of the jar are (3) a strongly convex or bulging neck plus three hollow conical feet, and (4) a high outcurving neck, rather sharp shoulder-body angle, and slightly concave base.

b. Pyriform vessels: (1) tapering to a relatively small orifice and supported by three hollow bulbous feet with single vents (in rear, on the side, or rarely in front) of wedge, ovoid, or slit shape; (2) same but bulbous shape; (3) same but effigy (hollow heads with square, wedge, ovoid, or slit vents), either animal (Fig. 131.7c–e) or human (Fig. 131.7a, b); frog effigies with concave base and no feet; (5) like 1 but with bell-shaped pedestal base instead of feet; (6) outcurving walls tapering to a relatively small orifice and angling convexly to a flat base, and supported by three hollow bulbous feet with the same vent pattern as 1; and (7) supported by a bell-shaped pedestal, one of which is of the rattle type (Fig. 131.12e).

c. Cylindrical vases with bell-shaped pedestal base.

d. Bowls: (1) hemispherical, a few with taper lip (not illustrated, but see Brainerd, 1941, pl. II, m) and all with flat bottom; (2) hemispherical supported by ring-stand; (3) subhemispherical with everted rim and flat bottom; (4) subhemispherical with direct rim and three hollow conical feet; (5) globular body, restricted orifice, and flat base; (6) globular body, restricted orifice or (7) with very low neck, both 6 and 7 being supported by three hollow bulbous or oven-shaped feet; (8) deep and nearly cylindrical, flat-bottomed; (9) barrel-shaped; and miscellaneous, including (10) two specimens with restricted orifice, shoulder-body angle, and flat base, and (11) two grater specimens with flaring walls angling to convex base and supported by three hollow bulbous feet.

e. Plates or dishes: (1) basal-break with three hollow bell-shaped or 2 bulbous feet, (3) same but flat-bottomed, and (4) basal-break receptacle with gutter spout, everted rim, and three hollow feet.

f. Drums of hand-bell shape.

g. A figurine container with a vertical tubular spout.

A few points of interest may be noted. A number of pyriform vases were cut down at the rim, possibly because of chipping or breakage (Figs. 131.6g, p, r; 131.10n), though it is hard to detect that some of them have been cut down and finished off at a lower level. One vessel (Fig. 131.16d) has four holes drilled through the wall on either side of a crack, evidence of lace mending of cracks. Finally, we note certain similarities: in shape of X Fine Orange to both Tohil Plumbate and Z Fine Orange vessels. Parallels with the former are numerous, as can be seen in the following list comparing our illustrations with those of Shepard (1948):

Jars. Figs. 131.1a, l; 131.13b; Shepard, Fig. 10a–e; Fig. 131.1a, 3; Shepard, Fig. 10j; Figs. 1a, 4; 4d; Shepard: Fig. 8c

Pyriforms. Figs. 131.1b, l; 131.6i; Shepard, Figs. 5,q; 11j; Figs. 131.1b, 3; 131.7a–f; Shepard, Fig. 5t; Figs. 131.1b, 4; 131.13o, p; Shepard, Fig. 14f, g; Figs. 131.1b, 5; Fig. 131, 10d; Shepard, Fig. 8g–i; Figs. 131.1b, 7; 131.12b–d, f; Shepard Fig. 8j.

Cylindrical vases. Figs. 131.1c; 131.12m; 131.17a–d; Shepard, Figs. 7d, g; 11m; 12e.

Bowls, Figs. 131.1d, 11; 131.5h, i; Shepard, Fig. 6d.

The X and Z Fine Orange matching forms are two, both bowls the hemispherical bowl with flat base and taper lip (see Brainerd 1941, Pl. II, m; X Fine Orange; Pl. III, t; Z Fine Orange); and the hemispherical bowl with stepped ring-stand base (Figs. 131.1d, 2, and 131, 4j; X Fine Orange; see Berlin, 1956, Fig. 3c, d, Z Fine Orange).

DECORATION

Techniques of Decoration (legend of Fig. 131.1). Nine techniques of decoration, rarely used singly but generally combined so that two or three are represented on a vessel, are exhibited in the collection: grooving, black painting, use of rim or body moldings, gouging-and-incising, modeling, polychrome painting, incising, dichrome painting, and stucco-and-painting.

Grooving, done before slipping, is usually applied as horizontal rim or body banding in conjunction with other techniques such as painting and gouging-and-incising. Rarely is it used by itself (Fig. 131, 1a, 3).

Black Painting is often applied with horizontal grooving or a rim molding. It is also used frequently with the gouged-and-incised and the modeled techniques. Occasionally black paint decoration is combined with gouging-and-incising through black and gouging-and-incising through white.

Moldings are produced by slicing back the vessel wall to form a clapboardlike horizontal step. With one exception (body moldings, Fig. 131.12e), the moldings are at the rim. Sometimes the molding is the only decoration (Fig. 131.13c), but it may be combined with several other techniques.

Gouging-and-Incising is a form of carving wherein the decoration is produced by scooping or gouging out small areas to accentuate an incised design. It is occasionally applied together with grooving and/or a rim molding. More often it is associated with black painted design. Less frequently it is combined not only with black design but also with a black or white background through which it is cut.

Modeling, used only with effigy vessels, usually involves an animal (Fig. 131.13h, j, k, m, n) or human (Fig. 131.13g, i, l) head attached (welded) to the vessel body wall. In a few specimens the limbs are modeled, but more often these, together with other details, are portrayed by means of black paint. The modeled limbs usually carry some incised as well as black details (Fig. 131.13o, p).

Polychrome Painting, is used with rim moldings on pyriform vessels (Fig. 131.14i–k), in which case it consists of red, black, and white on an orange slip. Another such vessel (Fig. 131.14, l) combines polychrome painting, black painting, and gouging-and-incising through white, and still another pyriform vase (Fig. 131.14g) is decorated in black-and-white-on-orange. Two bowls with red and black designs are embellished by a gouged-and-incised through white (Fig. 131.16e) and an incised through white (Fig. 131.16c) band. Two drums (Fig. 131.17g, i) have red-and-white-on-orange decoration, and one (Fig. 131.5m) has a red-and-black-on-orange arrangement. The only basal-break vessel with polychrome decoration has an interior rim band of black abstract motifs on a specular hematite red stripe (Figs. 131.51; 131.17e).

Incising, save for the details on modeled effigy limbs mentioned under modeling, and the more prevalent occurrence with gouging, is rare. Gouging and incising is a post-slip process. There is a single effigy vessel with the limbs formed by incising (Fig. 131.13, l). Incising is used to make "potter's marks" (Fig. 131.5n) on the base of five pyriform vessels (Figs. 131.8b; 131.10, 1; 131.11g; 131.14, 1; 131.15g) and on one basal-break tripod dish (Fig. 131.5j). Among 200 vessels examined, only six bear what evidently

are potter's marks, and these six are not outstanding, as might be expected for signed vessels, though none is crude. Another post-slip use for incising is a form of doodling or perhaps a post-finish attempt at further embellishment (Fig. 131.8h).

Dichrome occurs but twice. It consists of a horizontal red stripe on the interior. This decoration is not painted but is produced in the firing and therefore makes an uneven rim stripe (Fig. 131.4e). This same style of stripe is present on hemispherical bowls with taper lip, a few of which were in the Marquez collection but are not illustrated here (Brainerd 1941, Pl. II, m).

Stuccoed-and-painted decoration is present on one vase (Fig. 131.17d), on which vestiges of green stucco were scattered.

DESIGN STYLE (FIGS. 131.2, 131.3)

Design may be considered under four main headings: abstract, naturalistic, conventionalized, and glyphic. Nearly all the abstract design is found in banding, which may be one or more horizontal encircling bands. Naturalistic design occurs both in bands and as overall decoration. Conventionalized design is used in bands and in panels. Glyphic representation is always found in bands.

Abstract design is applied in several ways, specifically black painting, gouging-and-incising, and polychrome and dichrome painting. These methods occur separately (Fig. 131.2) or in various combinations (Fig. 131.3). In black painting the numerically predominant designs, all used in bands, are: step-fret, step-fret and V, concentric semicircles, and semicircles. Associated with the technique of gouging-and-incising, the principal designs, also used in bands, include: scroll meander, rectangle and circle, reverse curve, and braid. Accompanying polychrome horizontal striping and concentric circles in bands are the predominating designs, all others occurring but once each. Dichrome-designs are very rare, the only two noted being horizontal striping.

In respect to abstract design style, a close parallel exists between the gouged-and-incised scroll meander (Fig. 131.3c, 1, 2) and reverse curve (Fig. 131.3e) of X Fine Orange and the grooved simple scroll and related elements (Shepard 1948, Figs. 37c; 38b) and reverse curve design (Shepard 1948, Fig. 36d, f) of Tohil Plumbate.

Naturalistic design motifs all fall within the painted or modeled-and-painted categories. Like the abstract designs, they occur either as a single technique or in combination with other techniques of decoration. The outstanding painted motif is black birds (Fig. 131.3h, 1, 2), always represented in bands.

Other painted motifs are sometimes used as overall decoration (black hands, Fig. 131.3n), at other times represented in bands (serpents, Fig. 131.3m, and large birds, Fig. 131.3o). The modeled-and-painted representations include human (Fig. 131.3i), jaguar (Fig. 131.3k), frog (Fig. 131.3, 1), and monkey (Fig. 131.3, l).

Conventionalized design is applied in black, usually by means of gouging-and-incising, and rarely in polychrome: Again, these techniques are used either separately or in combination. The predominant motifs occurring in bands are floral, either bud-like (Fig. 131.3e, 1, 2) or quatrefoil (Fig. 131.3q, 1, 2). Other motifs include scroll grotesques, all gouged-and-incised, two found in panels (Figs. 131.10, 1; 131.12m), one in a band (Fig. 131.10c), and also a band of shell-like representations painted in black (Fig. 131.9d).

Glyphic Design occurs rarely, but appears both in black (Fig. 131.6f and by means of incising through white (Fig. 131.16c). The motifs are the *ilhuitl* sign and a kin-like sign, always in bands.

We have not yet considered floor decoration. Apart from the two graters, which have incised circles placed centrally and quartered, each quadrant being divergently hatched by incision, five vessels from this collection, three bowls and two tripod plates, have black painted floor designs. Two of the bowls have concentric circle motifs, one simple (Fig. 131.4k), the other with an outer zigzag line giving a starlike effect (Fig. 131.4g). The third bowl (Fig. 113.1a) shows an animal of some sort, possibly a dog or deer, on the floor, but it is weathered. One tripod plate has a floral design (Fig. 131.5j), the other an excellent turtle (Fig. 131.5k), painted on the floor and surrounded by a black step-fret, band.

SUMMARY

In this study of a large collection of well-preserved fine orange vessels we have examined ware, form, techniques of decoration, and styles of design. Since the paste of fine orange appears to the eye to be the same for all types, we must rely on form, techniques of decoration, and styles of design in determining whether or not a specimen is of X type.

Three-quarters of the vessels in this collection are pyriform; the function of this shape is not clear save that it is hardly utilitarian, seeming best adapted to ceremonial purposes. The other shapes, such as the jar, bowl, and dish, are all standard utility forms, but the vessels are so highly decorated that they appear to have been destined for ceremonial usage. All the X Fine Orange vessels so far found apparently were made for ritual use. Furthermore, most of the pyri-

form, effigy, and jar shapes are paralleled in Tohil Plumbate, which one can presume served primarily ceremonial purposes.

Of the decorative techniques on X Fine Orange vessels the most common is painting, usually black. Second comes gouging-and-incising, a technique closely associated with Early Classic Maya art. Another method of decoration is modeling, used in the forming of the heads and occasionally the limbs of animal and human effigy vessels. These effigy types are closely paralleled in Tohil Plumbate and Nicoya Polychrome. Rarely the heads may have been mold-made. As previously noted, four-color polychrome fine orange shares its commonest form with X Fine Orange, but the forms associated with three-color polychrome fine orange are rare in X Fine Orange. The decoration of these polychromes, the main differences in which involve design rather than technique suggests X Fine Orange, Cerro Montoso, and in some cases Classic Maya decoration.

Aside from the classification of design into abstract, naturalistic, conventionalized, and glyphic, there are four different styles presumably deriving from four traditions: the black-on-fine orange, the gouged-and-incised-on-fine orange, the red-black-and-white-on-fine orange, and the red-and-black-on-fine orange.

The black design patterns are mostly abstract and in interlocking bifold symmetry. The gouged-and-incised abstract patterns, on the other hand, are usually composed of elements different from those of the black and are arranged in slide reflection symmetry. The red-black-and-white design patterns have much in common with the black. Interlocking bifold symmetry and many of the same patterns, such as the step-fret, step-fret and V, concentric circle, and terrace and scroll, occur. Even a naturalistic serpent motif is represented, and there are a few conventionalized elements, including the quatrefoil and the shell. Save for the quatrefoil, and in one instance the stepfret, the gouged-and-incised designs are foreign to the red-black-and-white-on-fine orange style. To me, however, there is a clear association between this four-color polychrome and Maya Late Classic (Tepeu 2) style. In fact, both the black-on-fine orange and the red-black-and-white-on-fine orange design patterns resemble more closely those found in the Maya Late Classic period than do the design patterns habitually employed in the gouged-and-incised technique. These last have a close relationship with the Tohil Plumbate abstract design styles, both in patterns, such as simple scrolls and related elements, elaborate scroll bands (scroll meanders), and the reverse curve, and in the arrangement, which is usually slide reflection symmetry.

The fourth style, red-and-black-on-fine orange, has simple decoration; it is primarily striping, both horizontal and vertical. It has not yet been possible to associate this style with any definite tradition.

Interestingly enough, the same design elements, even the same design patterns, have been found in both the black-on-fine orange and the gouged-and-incised techniques, namely, the stepfret, reverse curve, braid, the ilhuitl sign, and floral devices. This fact leads me to believe that in this so-called Toltec period, perhaps better described as early post-Classic period, the Late Classic tradition is still so strong that it is reflected in separate bands, although frequently associated on the same vessel with a band or bands of pure early post-Classic style probably derived from the same tradition as that of the Tohil Plumbate abstract designs. In attempting to trace the abstract design tradition of Tohil Plumbate, however, we are faced with a difficult and complicated problem. For instance, the most important design element is the scroll, which goes back to pre-Classic times and continued to be used throughout Mesoamerica until after the arrival of the Spaniards. It does not seem to be related to the scroll used in the Classic Veracruz style as delineated by Proskouriakoff (1953), or to the Early Classic scroll patterns at Uaxactun (Smith 1956). Moreover, although there is a rather close similarity between this device as found at Uaxactun and Monte Alban (Bernal 1949), the Monte Alban style appears to offer more parallels to gouged-and-incised X Fine Orange and to Tohil Plumbate than does the Uaxactun style.

We have noted that fine orange polychrome occurs in two varieties, three-color and four-color. The latter, wherever found, is usually associated with X Fine Orange. It conforms to the X Fine Orange type in ware, in design, and in its most common shape. In the matter of design, X Fine Orange fostered two styles: the black, which suggests a Classic Maya tradition; the gouged-and-incised, which parallels the Toltec style. The fine orange four-color polychrome also shows the Classic Maya and Toltec styles of design, often on the same vessel. It seems to me, therefore, that fine orange four-color polychrome, if not included in the X Fine Orange type, is at least closely associated

ABBREVIATIONS AND FREQUENCIES OF DECORATIVE TECHNIQUES (FIGS. 131.1–131.3)

FIG. 131.1. VESSEL SHAPES, DIMENSIONS, AND TECHNIQUES OF DECORATION.

a. Jars

1. Standard: lip diam. 9.0–9.8 cm, av. 9.3 cm; max. diam. 15.0–17.1 cm, av. 16.5 cm; base diam. 6.0–7.1 cm, av. 6.6 cm; neck ht. 4.7–5.0 cm, av. 4.9 cm; overall ht. 14.8–17.2 cm, av. 16.2 cm; wall thickness 0.3–0.5 cm to 0.5–0.6 cm, av. 0.4–0.6 cm. B (1), Gr (1), U (1).

2. Flaring-neck: lip diam. 15.5 cm, max. diam. 26.3 cm, base diam. 10.5 cm, neck ht. 3.0 cm, overall ht. 23.2 cm, wall thickness 0.5–0.7 cm. B (1).

3. Bulbous-neck tripod: lip diam. 7.4 cm, max. diam. 13.2 cm, overall ht. 13.7 cm, wall thickness 0.3–0.6 cm. Gr (1).

4. High-neck, angled-body; lip diam. 9.2 cm, max. diam. 14.0 cm, base diam. 5.0 cm, neck ht. 5.5 cm, overall ht. 14.0 cm, wall thickness 0.5–0.6 cm. BMo (1).

b. Pyriform Vessels

1, 2. Tripods, typical pear-shaped, and more globular body: lip diam. 5.3–8.7 cm, av. 6.8 cm; max. diam. 9.5–15.5 cm, av. 12.4 cm; overall ht. 12.6–18.4 cm, av. 15.0 cm; wall thickness 0.3–0.6 cm, av. 0.37–0.55 cm. B (14), BGI (3), BGIB (2), BGIW (1), GI (1), RMo (9).

3. Tripod effigy: lip diam. 5.3–7.6 cm, av. 6.3 cm; max. diam. 10.5–15.2 cm, av. 12.5 cm; base diam. 4.5–

131.1. Vessel shapes, dimensions, and techniques of decoration.

6.6 cm, av. 5.7 cm; overall ht. 13.7–18.9 cm, av. 15.4 cm; wall thickness 0.3–0.9 cm, av. 0.35–0.55 cm. M (1), MB (14), MI (1).

4. Effigy: lip diam. 6.6–7.1 cm, max. diam. 14.8–17.6 cm, base diam. 5.2–6.5 cm, overall ht. 11.0–13.0 cm, wall thickness 0.3–0.6 cm. MI (2).

5. Pedestal-based: lip diam. 5.2–8.3 cm, av. 6.6 cm; max. diam. 8.0–13.7 cm, av. 10.9 cm; base diam. 7.2–12.1 cm, av. 9.6 cm; overall ht. 10.5–22.9 cm, av. 16.9 cm; wall thickness 0.2–0.8 cm, av. 0.4–0.57 cm. B (32), BGI (13), BGIW (2), P (5), RMo (3).

6. Tripod with body-base angle: lip diam. 5.0–9.0 cm, av. 6.4 cm; max. diam. 9.5–16.0 cm, av. 11.7 cm; base diam. 4.0–6.0 cm, av. 4.7 cm; overall ht. 12.7–20.5 cm, av. 16.6 cm; wall thickness 0.2–0.8 cm, av. 0.36–0.56 cm. B (9), BGI (25), BGIB (2), BGIW (1), GI (2), RMo (1).

7. Pedestal-based, with body-base angle: lip diam. 5.6–7.1 cm, av. 6.3 cm; max. diam. 9.8–11.2 cm, av. 10.5 cm; base diam. 9.0–10.8 cm, av. 9.9 cm; overall ht. 18.9–20.8 cm, av. 19.7 cm; wall thickness 0.2–0.6 cm, av. 0.34–0.54 cm. B (2), BGI (3), GI (1), PBGIW (1).

c. Cylindrical Pedestal-Based Vases: lip diam. 7.0–13.2 cm, av. 9.8 cm; max. diam. 8.8–11.8 cm, av. 9.8 cm; base diam. 8.3–13.3 cm, av. 11.2 cm; overall ht. 11.5–23.2 cm, av. 19.7 cm; wall thickness 0.3–0.7 cm, av. 0.5 cm. B (5), BGI (1), BGIB (1), GI (1), RMo (2).

d. Bowls

1. Hemispherical: lip diam. 11.9–34.0 cm, av. 22.2 cm; base diam. 4.5–9.5 cm, av. 7.3 cm; overall ht. 5.1–12.2 cm, av. 8.2 cm; wall thickness 0.5–1.0 cm, av. 0.57–0.85 cm. B (1), D (1), P (1), U (1).

2. Hemispherical ring-stand: lip diam. 14.5–21.4 cm, av. 16.6 cm; base diam. 7.0–11.0 cm, av. 8.9 cm; overall ht. 6.5–7.3 cm, av. 7.1 cm; wall thickness 0.4–0.8 cm, av. 0.43–0.58 cm. B (1), BGIW (1), D (1), RMo.

3. Subhemispherical, with everted rim: lip diam. 30.8–37.0 cm, base diam. 11.0 cm, overall ht. 10.5–14.0 cm, wall thickness 0.6–0.8 cm. BGIW (1), PIW (1).

4. Subhemispherical tripod: lip diam. 27.5–31.0 cm, av. 29.4 cm; base diam. 8.5–12.5 cm, av. 10.0 cm; overall ht. 13.2–15.4 cm, av. 14.1 cm, wall thickness 0.5–1.0 cm, av. 0.59–0.75 cm. BGIB (1), PGIB (2), PGIW (1).

5. Restricted-orifice: lip diam. 5.0–5.6 cm, max. diam. 8.8–9.9 cm, overall ht. 6.9–7.0 cm, wall thickness 0.4–0.8 cm. B (2).

6. Restricted-orifice tripod: lip diam. 4.7 cm, max. diam. 12.9 cm, overall ht. 13.4 cm, wall thickness 0.3–0.5 cm. BGI (1).

7. Low-necked tripod: lip diam. 6.0–6.5 cm, max. diam. 12.0–12.6 cm, overall ht. 12.3 cm, wall thickness 0.4–0.8 cm. GI (1), Gr (1).

8. Cylindrical deep: lip diam. 15.4 cm, base diam. 8.9 cm, overall ht. 10.3 cm, wall thickness 0.4–0.5 cm. B (1).

9. Outcurving-sided deep: lip diam. 9.0 cm, max. diam. 13.4 cm, base diam. 7.7 cm, overall ht. 13.0 cm, wall thickness 0.5–0.7 cm. Gr (1).

10. Restricted-orifice angle-sided: lip diam. 11.1–11.7 cm, max. diam. 16.3–19.2 cm, base diam. 9.5 cm, overall ht. 8.8–10.8 cm, wall thickness 0.3–0.5 cm. B (1), BGIW (1).

11. Tripod grater: lip diam. 18.8–19.1 cm, overall ht. 11.3–11.5 cm, wall thickness 0.5–0.6 cm. B (2).

e. Plate and Dishes

1. Tripod basal-break plate: lip diam. 28.0 cm, base diam. 22.2 cm, overall ht. 10.2 cm, wall thickness 0.6–0.9 cm. B (1).

2. Tripod basal-break dish: lip diam. 17.5 cm, base diam. 12.0 cm, overall ht. 7.0 cm, wall thickness 0.5 cm. B (1).

3. Flat-based basal-break dish: lip diam. 14.0 cm, base diam. 9.5 cm, overall ht. 3.0 cm, wall thickness 0.3–0.4 cm. P (1).

4. Tripod basal-break dish with gutter spout: lip diam. 15.0 cm, base diam. 11.7 cm, overall ht. 5.5 cm, wall thickness 0.4–0.8 cm. GIW (1).

f. Drums: lip diam. 8.1–9.6 cm, av. 9.1 cm; max. diam. 7.7–8.5 cm, av. 8.2 cm; base diam. 5.1–6.0 cm, av. 5.7 cm; overall ht. 15.1–17.9 cm, av. 16.9 cm; wall thickness 0.3–0.5 cm, av. 0.3–0.5 cm. P (3).

g. Spouted Effigy Vase: overall ht. 19.0 cm. MP (1).

Scale is 1/6.

FIG. 131.2. STYLES OF DESIGN PRIMARILY PAINTED ABSTRACT.

a. Horizontal stripes and/or lines, B (numerous), Gr (numerous), P (3), D (2); *b.* Step-fret, B (37), GI (1), P (1); *c.* Step-fret and V, B (22), P (1); *d.* Concentric semicircles, B (13); *e.* Semicircles, B (11); *f.* Beaks or snouts, B (11); *g.* Concentric circles, B (4), P (2); *h.* Figure eight and other elements, B (6); *i.* Scroll border, B (6); *j.* "Down-balls," B (6); *k.* Dotted line, B (5); *l.* Terrace and other elements, B (4), P (1); *m.* S and pendant lines, B; *n.* Guilloche, B (3); *o.* Step and other elements, B (3); *p.* Pendant lines, B (2); *q.* Hook and vertical lines, B (2); *r.* Vertical lines joined at top, B (2); *s.* Circles, B (2); *t.* Rectangles, B (1), P (1); *u.*

131.2. Styles of design: primarily painted abstract.

Horizontal and vertical striping, P (2); v. Semidisks, B (1); w. Concentric triangles, P (1); x. Trefoil and cross, P (1); y. Star and hook, P (1).

**FIG. 131.3. STYLES OF DESIGN
ABSTRACT, NATURALISTIC,
CONVENTIONALIZED, GLYPHIC.**

a, b. Primarily painted abstract designs.

a. hand bells and scrolls, P (1).

b. miscellaneous: 1. V, hook, squiggle, and pendant lines, BGIW (1); 2. squiggle, B (1); 3. triangle and U band, BGI (1); 4. U band, BGI (1); 5. guilloches, circle and dots, and V's, BGI (1).

c-g. Primarily gouged-and-incised abstract designs.

c. scroll meander, GI (27), GIB (6), GIW (3), B (2).

d. rectangles and circles, GI (7), GIW (2).

e. reverse curve, GI (4), GIW (2), B (1).

f. braid, GI (5), B (1).

g. scroll and other elements, GI (4).

h-o. Primarily black or modeled and black naturalistic designs.

h. black birds, B (24).

i. human effigy, MB (8), B (1).

j. effigy frogs, MI (3), MB (2).

k. effigy jaguars, MB (3), MP (1).

l. effigy monkey, MB (1).

m. serpents, B (2), P (1).

n. hands, B(1).

o. large birds, B (2).

p-s. Primarily gouged-and-incised conventionalized designs.

p. budlike floral designs, GI (9), B (5).

q. quatrefoils GI (5), B (1), P (1).

r. scroll grotesques, GI (3), P (1).

s. shell. B (1).

t, u. Mostly gouged-and-incised glyphic motifs.

t. *ilhuitl* signs, B (2), GI (2).

u. kin-like sign, GI (1).

**FIG. 131.4. JARS AND BOWLS WITH
BLACK PAINTED AND GOUGED-
AND-INCISED DECORATION.**

a-d. Jars. *a.* tripod with bulbous neck, body groove; *b.* standard, decorated with black serpents; *c.* globular body and flaring neck, black step-fret and V band; *d.* angled body and high neck, body and neck moldings.

e-g. Hemispherical bowl; *e.* interior red band; *f.* exterior black band of concentric circles; *g.* interior floor design, black.

h-j. Hemispherical ring-stand bowls. *h.* interior red band; *i.* exterior black bird band; *j.* interior band, of black semi-disks, and exterior gouged-and-incised step-fret band with black stripe below.

k, l. Subhemispherical tripod bowls; *k.* interior horizontal black rim stripes and concentric circle floor design, exterior gouged-and-incised through black scroll meander; *l.* interior horizontal red and black stripes, exterior gouged-and-incised through black upper band with scroll meander and floral bud designs and lower band of black beaks or snouts. Scale is 1/4.

**FIG. 131.5. BOWLS, PLATES, DISHES,
DRUM WITH BLACK, GOUGED-AND-
INCISED, AND GROOVED DESIGN.**

a, b. Restricted-orifice bowls; *a.* exterior rim band of black "down-balls" (Thompson 1950:113); *b.* exterior rim band of black step-fret and V's.

c. Restricted-orifice tripod bowl with gouged-and-incised reverse curve band framed by black stripes and band of beaks or snouts.

131.3. Styles of design: abstract, naturalistic, conventionalized, glyphic.

131.4. Jars and bowls with black painted and gouged-and-incised decoration.

d. Low-necked tripod bowl grooved horizontally and vertically, giving gadrooning effect.

e. Nearly cylindrical deep bowl with vertical black stripes and rim molding.

f. Barrel-shaped deep bowl grooved vertically and with modeled disks.

g. Restricted-orifice angle-sided bowl with step-fret black rim band.

h, i. Tripod grater bowls; *h.* exterior black bird band; *i.* exterior black step-fret band.

j. Tripod basal-break dish having hollow bell-shaped feet, black floral floor design, black dots on red lip band, exterior black step, hook, and V band, and an incised potter's mark on base (Fig. 5n, 4).

k. Tripod basal-break dish having hollow bulbous feet and decorated with exterior black step-fret band, interior black step-fret rim band, and black turtle floor motif.

l. Flat-based basal-break dish with interior specular hematite red rim stripe with a badly weathered black design.

m. Hand-bell-shaped drum with red and black decoration.

n. Incised "potter's marks" on vessel bases (1, Fig. 8b; 2, Fig. 10,1; 3, Fig. 11g; 4, Fig. 5j; 5, Fig. 15g.).

Scale is 1/4.

FIG. 131.6. PYRIFORM TRIPOD VESSELS ALL HAVING HOLLOW BULBOUS FEET AND MOST HAVING RIM MOLDINGS.

a-d. Black step-fret bands; *c.* lower band of black birds separated from upper band by three horizontal encircling grooves; *d.* lower S band.

e-g. Black step-fret bands; *e.* lower band of black step-frets separated from upper band by three horizontal encircling grooves; *f.* lower band of black il-

huitl signs; *g.* tapering neck cut down; lower band of black split terraces, tau's, and v's.

h. Black figure eight band framed by paired horizontal black lines.

i. Black upper band of hooks separated by parallel vertical lines, lower band of black figure eights, black horizontal lines, and grooved U band in between. Two black bands, upper of concentric circles, lower of circles.

k. Two black bands, upper of birds, lower of scrolls.

l. Two black bands, upper of floral buds, lower of pendant lines.

m. Band of black floral panels bordered by band of U's.

n. Undecorated save for rim molding.

o. Gouged-and-incised band of scrolls and terraces.

p-r. Gouged-and-incised through black bands of scroll meanders.

p. lower black band of beaks or snouts.

q. lower black concentric semicircle band. *r,* tapering neck cut down. Scale is 1/4.

FIG. 131.7. EFFIGY JARS OR PYRIFORM VESSELS.

a, b. Human figures with modeled heads and black painted bodies.

c-e. Animal figures with modeled heads and black painted bodies; *c.* head missing; *d, e.* jaguars.

f. Human head, no visible decoration on body.

g. Monkey, head missing, arms, legs, and tail modeled and painted black.

Scale is 1/4.

131.5. Bowls, plates, dishes, drum with black, gouged-and-incised, and grooved designs.

131.6. Pyriform tripod vessels.

131.7. Effigy jars or pyriform vessels.

FIG. 131.8. PYRIFORM VESSELS WITH BELL-SHAPED PEDESTALS, RIM MOLDINGS, AND BODIES DECORATED WITH BLACK DESIGNS.

a–j. Step-fret bands; *b.* incised potters mark on base (Fig. 5n, 1); *f.* bordered by lines of semi-disks and dots; *g.* bordered by lines of dots and semi-circles; *h.* two step-fret bands with lower border of semicircles, post-slip basal band of V's; *i.* lower border of semicircles; *j.* lower border of vertical lines joined at bottom.

k. Step-fret and V band with lower border of concentric semi circles.

l. Step and V band.

m. Semidisk rim border, upper band of terraces and hooks, lower of step-frets and V's.

n. Two bands, upper a braid, lower of steps, V's, and O's.

o. Step-fret and V band with lower scroll border.

p. Band of concentric circles separated by paired vertical parallel lines and framed by paired horizontal lines.

q. Guilache band.

r. Body band of steps and hooks with lower border of beaks or snouts, pedestal band of snake rattles.

s. Band and lower border of S's and pendant lines.

t, u. Black bird bands; *t.* lower border of concentric semi circles.

v. Two bands, upper of quatrefoils, lower of step-frets.

w. Semidisk rim border and floral bud band with lower border of scrolls.

Scale is 1/4.

FIG. 131.9. PYRIFORM VESSELS WITH BELL-SHAPED PEDESTALS AND RIM MOLDINGS.

a, b, e. Black naturalistic motifs. *a, e.* feathered rattlesnakes; *e* has black squiggle rim band; *b.* large

bird band framed by black step-fret and black scroll band.

c. Black glyphic band of *ilhuitl* signs separated by steps.

d. Black conventionalized shell band.

f–l. Gouged-and-incised scroll meander bands plus black bands; *f.* lower black beak or snout band; *g.* upper black dot band, lower black beak or snout band; *h.* lower band of black scroll meanders; *i.* lower band of black step-frets; *j.* lower band of black step-frets and V's; *k.* upper band of black steps, U's and circles and dots; lower band of black guilloches, V's, and circles and dots; *l.* lower band of black step-frets and V's.

m. Gouged-and-incised bands of rectangles and circles and bud like motifs framed by black bands of S's and pendant lines. Scale is 1/4.

FIG. 131.10. PYRIFORM PEDESTAL-BASED VESSELS AND PYRIFORM TRIPODS WITH BODY-BASE ANGLE.

a–d. Pyriform pedestal-based vessels; *a.* gouged-and-incised budlike band framed by upper black band of step-frets and V's and lower border of black dots; *b.* gouged-and-incised quatrefoil band with lower band of black birds and border of black concentric semicircles; *c.* gouged-and-incised scroll grotesque band framed by paired horizontal black lines and bordered at bottom by black triangles and squiggles; *d.* gouged-and-incised floral band framed by black step-fret and black beak or snout bands.

e–o. Pyriform tripods with body-base angle; *e–k,* black painted abstract designs. *e,* step-fret band; *f.* upper band of step-frets, lower band of step-frets and V's; *g, h,* upper and lower bands of step-frets and V's; *i.* upper band of reverse curves, lower band of step-frets and V's; *j.* upper band of step-frets and V's, lower band of guilloches"; *k.* upper band scroll meander, lower band of "down-balls."

l–o. Gouged-and-incised in all cases, may have black design as well; *l.* two bands of gouged-and-incised budlike panels alternating with gouged-and-incised through black budlike and quatrefoil panels, incised potters mark on base (Fig. 131.5n, 2); *m.* gouged-and-incised through black scroll meander upper band, lower band of black birds; *n.* gouged-and-incised scroll meander band; *o.* two gouged-and-incised *ilhuitl* sign bands.

Scale is 1/4.

131.8. Pyriform vessels with bell-shaped pedestals, rim moldings, and bodies decorated with black designs.

131.9. Pyriform vessels with bell-shaped pedestals and rim moldings.

131.10. Pyriform pedestal-based vessels and pyriform tripods with body-base angle.

FIG. 131.11. PYRIFORM TRIPOD VESSELS WITH BODY-BASE ANGLE.

a–k. All have gouged-and-incised scroll meanders plus other black designs. *a, c–j.* black bird bands; *d* also has black beak or snout border; *g.* also has incised potter's mark on base (Fig. 131.5n, 3); *k.* black figure eight.

l. Gouged-and-incised scroll meander band framed by rectangle and circle bands, upper band of black step-frets and V's, lower band of black concentric circles.

m, n. Gouged-and-incised braid upper band, black bird lower band.

o, p. Gouged-and-incised reverse curve bands; *o.* lower black bird band; *p.* lower black band of semicircles and dots.

q. Gouged-and-incised quatrefoil band with lower black bird band.

r, s. Gouged-and-incised budlike bands; *r.* lower black band of semicircles and dots; *s.* upper black rectangle band, lower black band of S's and pendant lines.

Scale is 1/4.

FIG. 131.12. PYRIFORM PEDESTAL-BASED VESSELS WITH BODY-BASE ANGLE AND CYLINDRICAL PEDESTAL-BASED VASES.

a–g. Pyriform pedestal-based vessels with body-base angle; *a.* central black budlike band framed by upper black stepfret and lower black semicircle bands; *b.* central black budlike band framed by upper black step-fret and V and lower black semicircle bands; *c.* gouged-and-incised central bands of rectangles and circles and braid motif framed by upper black step-fret and lower black "down-ball" bands; *d.* gouged-and-incised upper band of reverse curves with band of black "down-balls" and band of black concentric semicircles below; *e.* hollow rattle pedestal, three gouged-and-incised bands of scroll meanders, upper two separated by molding probably painted black (weathered), lower bands divided by three horizontal grooves; *f, g.* central gouged-and-incised budlike band framed by horizontal black lines and black lines and lower band of black step-frets.

h–m. Cylindrical pedestal-based vases with multiple banding; *h.* three black bands including upper

step-fret and V, middle figure eight, lower vertical lines joined at top; *i.* three black bands, two upper of "down-balls," lower of concentric semicircles; *j.* three black bands, two upper of figure eights, lower of concentric semicircles; *k.* upper black step-fret, lower black semicircle bands; *l.* upper scroll meander band gouged-and-incised through black, middle black "down-ball" band, lower black scroll band; *m.* two gouged-and-incised scroll grotesque panels with gouged-and-incised band of scrolls, U's, and tau's below.

Scale is 1/4.

FIG. 131.13. JARS, PYRIFORM VESSELS, EFFIGIES.

a, b. Standard jars; *a.* darkened body area; *b.* gadrooned body (worked from exterior).

c, d, f. Pyriform tripods with bulbous bodies; *c.* darkened body area; *d.* black step-fret band; *f.* upper scroll meander band gouged-and-incised through white, lower S and pendant lines black band.

e. Pyriform tripod with body-base angle, grooved and gouged-and-incised with central band of quatrefoils framed by bands of rectangles and concentric circles.

g–n. Effigy vessels with hollow modeled heads; *g.* human head without other visible decoration and hollow bulbous feet; *h.* frog with black body details and hollow bulbous feet; *i.* human with black body details and hollow bulbous feet; *j.* frog with black body details and four solid slab feet; *k.* monkey with black body details and hollow bulbous feet; *l.* human with black body details and hollow bulbous feet; *m.* frog with black body details and hollow bulbous feet; *n.* frog with black body details and solid animal feet.

o, p. Frog effigy vessels with flat bases and decorated with modeled and incised frog limbs and feet; both show darkened body area.

FIG. 131.14. PYRIFORM VESSELS WITH PEDESTAL BASES.

a, b. Black design; *a.* central band of step-frets and V's framed by upper band of "down-balls" and lower band of semicircles.

b. all-over bands and scrolls.

131.11. Pyriform tripod vessels with body-base angle.

131.12. Pyriform-based vessels with body-base angle and cylindrical pedestal-based vases.

131.13. Jars, pyriform vessels, effigies.

c. Gouged-and-incised scroll meander upper band, black stepfret and V lower band.

d. Two gouged-and-incised scroll meander bands.

e. Gouged-and-incised scroll meander upper band, black concentric semicircle lower band.

f. Two upper gouged-and-incised scroll meander bands, black lower band of semicircles.

g. Black-and-white-on-orange; step-fret and V upper band, concentric circle lower band. This appears to be Cerro Montoso Fine Polychrome.

h. Red-black-and-white-on-orange; concentric triangle upper band, parallel vertical alternating red, white, and black lines in lower band.

i-k. Red-black-and-white-on-orange; *i.* conventionalized serpent's jaw (?) motif upper band, step-fret lower band, incised potter's mark on base (similar to Fig. 131.5n, 1); *j.* central band of concentric circles separated by paired vertical lines, upper and lower bands of terrace motifs; *k.* upper band of crosses and U's, lower band of shells and rattlesnakes.

l. Vessel with body-base angle and pedestal base; gouged-and-incised through white scroll grotesque central band framed by upper black-and-white hand bell and scroll band and lower band of black semicircles.

FIG. 131.15. PYRIFORM TRIPOD VESSELS.

a-i. Vessels with body-base angle; *a.* darkened area on body; *b.* two black step-fret bands; *c.* upper band of four grooves framed by paired horizontal black stripes, lower black terrace band; *d.* gouged-and-incised scroll meander band framed by paired horizontal black stripes; *e.* central gouged-and-incised scroll meander band framed by upper black step-fret and lower black semicircle band; *f.* central gouged-and-incised rectangle and circle band framed by upper gouged-and-incised braid band and lower band of black "down-balls"; *g.* central gouged-and-incised scroll meander band framed by upper band of paired horizontal black stripes and lower band of black birds, incised potters mark on base (Fig. 131.5n, 5); *h.* central gouged-and-incised braid band framed by upper band of paired horizontal black

stripes and lower band of black step-frets and V's; *i.* central band of gouged-and-incised rectangles and circles framed by upper gouged-and-incised scroll meander band and lower band of black V's, hooks, squiggles, and pendant lines.

FIG. 131.16. BOWLS.

a. Hemispherical bowl with black deerlike head on floor and exterior black bird band.

b, c. Hemispherical bowls with everted rims; *b.* interior black rim band of semidisks and semicircles, exterior upper gouged-and-incised band of scrolls and other elements and lower band of black beaks or snouts; *c.* black-on-white rectangle, circle, and triangle interior lip band, exterior incised through white kinlike upper band and rectangle and circle incised through red lower band.

d, e. Hemispherical tripods with hollow conical feet; *d.* interior rim band of black rectangles, exterior gouged-and-incised through white guilloche band with black horizontal stripes below; *e.* flat lip with band of black and red rectangles, exterior gouged-and-incised through white band of reverse curves with two horizontal black stripes below.

f. Low-necked tripod bowl with gouged-and-incised bands, central quatrefoil band framed by rectangle and circle bands. Restricted-orifice angle-sided bowl with two exterior bands, upper a gouged-and-incised budlike motif, lower of black concentric semicircles.

FIG. 131.17. CYLINDRICAL PEDESTAL-BASED VASES, TRIPOD DISHES, DRUMS, EFFIGY VESSEL.

a-d. Cylindrical pedestal-based vases; *a.* undecorated but large darkened area over most of body; *b.* two black bands, upper of birds, lower of concentric semicircles; *c.* gouged-and-incised rectangular panel with seated human figure framed by rectangle and circle bands. *d.* two gouged-and-incised panels enclosing scroll grotesques, gouged-and-incised scroll, U, and tau band below; traces of green stucco.

e. Tripod basal-break dish with hollow bell-shaped feet, black floral floor design, black dots on flat red lip, black step, hook, and V exterior band, and incised potters mark on base (Fig. 131.5n, 4).

Introduction

Theoretical Approaches to Problems is the fourth volume in the Carnegie Maya series, a publishing initiative by the University Press of Colorado to reissue the results of archaeological and anthropological investigations by the Division of Historical Research, Carnegie Institution of Washington, in southern Mesoamerica. Titles previously published in the series include excerpts summarizing the annual reports of the Division of Historical Research from 1913 through 1957 (*Carnegie Maya I*), the *Current Reports* that summarize the results originally published from 1952 to 1957 of the final CIW excavation program at Mayapan in northern Yucatan, Mexico (*Carnegie Maya II*), and *Notes on Middle American Anthropology and Anthropology*, a collection of various reports originally published from 1940 to 1957 (*Carnegie Maya III*). The fifth and final title in the series will republish the *Contributions to American Archaeology*.

The history and many accomplishments, and criticisms as well, of the Carnegie Maya program are presented elsewhere (Weeks and Hill 2006) and need not be repeated again. From 1914 to 1958 the Carnegie Institution of Washington sponsored archaeological and other investigations throughout the Maya region of southern Mexico and northern Central America. During these four decades the Carnegie Institution was the leader in the field, with monetary and human resources that no university or other research program could match, then or since. The more than 300 publications produced by Carnegie-supported researchers remain an impor-

tant, indeed essential, resource for modern scholars. The Carnegie Institution of Washington program is no more, although its framework has been modified, expanded, and replaced by several generations of new scholars. Its legacy stands as a firm foundation on which an entire discipline has been constructed.

The goal of the *Theoretical Approaches to Problems* series was clearly not to present final papers approaching a complete synthesis of Mesoamerican archaeology and anthropology as a result of the Carnegie Institution program. Rather, as the editor J. Eric S. Thompson (1941:i) states in his General Preface, the purpose of the series was to “outline tentative solutions which conform to information now at hand, with the purpose not of supplying final answers but of stimulating interest in these problems,” and to offer a “platform for such reconstructions and they are so clearly labeled as tentative that their authors will not be called on to stand by the ideas they advance.” The intention was simply to publish preliminary conclusions that “may later be reissued in modified form as a result of the flow of information that will, it is hoped, be stimulated by their publication.” Finally, Thompson makes clear that the series will serve to counterbalance the overspecialization that was replacing the broad comprehension of earlier generations.

By the 1930s, scholars generally recognized the Gulf Coast of southern Mexico as the heartland of the art style known as “Olmec” (Marcus 1976). Systematic excavation did not begin until 1939 when archaeologist Matthew Stirling conducted long-term

field investigations of Olmec sites with support from the Smithsonian Institution and the National Geographic Society. These included Tres Zapotes in 1939 and 1940, Cerro de las Mesas in 1940, La Venta in 1942 and 1943, and San Lorenzo in 1945 and 1946 (Stirling 1943).

The site of Tres Zapotes includes about fifty mounds and extends for three kilometers along the Arroyo Hueyapan near Chacalapa in the Mexican state of Veracruz. The mounds are separated into four plaza groups. Immediately in front of the principal mound of Group C, the easternmost cluster, was found Stela C, with a flat stone altar set in front of it. On the front of the monument was a “jaguar mask” panel, and on the back was a column of bars and dots placed horizontally. The numbers are not accompanied by period glyphs, but on the basis of position-value notation, Stirling reconstructed the Long Count date as [7].16.6.16.18. He predicted that the top half would include the Initial Series Introducing Glyph and the number 7, for Baktun 7, and the date would correlate to 32 BCE. He argued further that the Olmec was the mother culture for Mesoamerica, far earlier than the Maya civilization (Stirling 1939, 1940b).

There was great opposition to this position, especially by the Mayanists Sylvanus G. Morley and J. Eric S. Thompson, who regarded Olmec culture as a Classic period derivative of Maya civilization. The date was, however, accepted by the Mexican scholars Alfonso Caso, Miguel Covarrubias, and Roman Piña Chan, who argued that the Olmec represented the earliest civilization in Mesoamerica (Tellenbach 1978). In “Dating of Certain Inscriptions of Non-Maya Origin,” the first essay in *Theoretical Approaches to Problems*, J. Eric S. Thompson takes up the issue of dating inscriptions of non-Maya origin. He argues that the early inscriptions from southern Veracruz and the Pacific coastal plain of Guatemala, characterized by bars and dots between glyphs with numerical coefficients, are not Maya Initial Series but rather belong to a secondary series founded on the 400-day year. In essence, Thompson was taking on Stirling’s Stela C dating and detailed the evidence necessary to downgrade the dating of the Olmec (Tozzer 1942).

Stirling was proven correct in 1970, when the top half of Stela C was discovered by a local farmer, and the earlier date of 7.16.6.16.18, or 32 BCE, was confirmed. Another twenty to thirty years of dirt archaeology and radiocarbon samples collected at La Venta and San Lorenzo in the 1950s and 1960s demonstrated an even earlier placement of Olmec culture, prior to 400 BCE (Coe 1981:xi; Drucker, Heizer, and Squier 1957; Coe and Diehl 1980). Since

1939 only one older Long Count date has been discovered, on Stela 2 from Chiapa de Corzo, Chiapas, with a date of 7.16.3.2.13 (36 BCE). Stela C from Tres Zapotes remains one of the oldest dated monuments in the New World. More recent excavations have documented the development of the Olmec out of still earlier Formative cultures (Coe 1957).

In the second essay Thompson considers the fish as a Maya symbol for counting and explores directional glyphs. Thompson’s demonstration that *xoc*, or “count,” was represented in the inscriptions by the head of a large fish—the *xoc* or “shark”—was one of the discoveries that did the most to reopen some of the important questions about the fundamental nature of Maya script. Substituting for *xoc* in many inscriptions was the glyph T511, also found for the day Muluc. Since *xoc* shark is a patron deity of the day Muluc, Thompson assumed that the *xoc* head was the head form of the *muluc* glyph. This implied a straightforward rebus use for *xoc* and a symbolic secondary meaning for *muluc*, which he apparently thought should be read as *xoc* in this context.

Two “directional count glyphs” have long been recognized as the indicators of backward and forward chronological reckonings in Maya inscriptions. Their traditional decipherment, following Thompson, is based on reading *xoc*, “to count,” for one of the frequent signs in these glyphs. Stuart (1990) questions this reading by suggesting that all “count” glyphs are read *u-ti*, spelling the verb *ut*, “to come to pass.” This decipherment applies to all known contexts of the glyphs. Thompson’s original *xok ti* reading, later expanded by others to account for some variant forms, has gained wide acceptance among epigraphers. Stuart (1990), however, finds evidence for the *ut*, “to happen, come to pass,” decipherment more compelling.

The third essay, by John M. Longyear III, addresses the delineation of the limits of Maya civilization along the southern periphery of Mesoamerica. In the early 1940s, Longyear located and mapped many sites east of the Lempa River in El Salvador under the auspices of the Institute for Andean Research (Longyear 1944, 1951a, 1966). This was followed by several seasons working for the Carnegie Institution of Washington on the ceramic sequence at Copan in western Honduras (Longyear 1940a, 1940b, 1942, 1946, 1948, 1951b, 1952, 1957, 1969). His investigations identified the major local pottery types and determined the succession of the principal ceramic periods. He also identified numerous pieces of nonlocal or exotic manufacture, which stimulated questions about chronological relations and commercial contacts within and outside of the

Maya area. Longyear's study area was the frontier where Mesoamerican and non-Mesoamerican cultures met and presumably influenced each other. Scholars are still puzzling over the problem of just how far south the Maya expanded from their presumed homeland. Samuel K. Lothrop (1939) was the first to deal with the question of the southern frontier of the Maya, and his research was the foundation for a number of later studies, including Longyear's essay in *Theoretical Approaches to Problems*. Lothrop first placed the maximum limit of Maya penetration in Honduras east of Lake Yojoa and in El Salvador along the Lempa River. His approach was essentially ahistorical, linking sixteenth-century accounts of the Maya with what he considered to be Maya pottery. While taking Lothrop to task for making these connections, Longyear accepts the equally troublesome proposition that linguistic groups formed distinct archaeological cultures (Linares 1979). Arguing that there is very little that was Maya in the Ulua-

Yojoa archaeological complex, he places the Maya frontier during Classic times further to the west in Honduras, roughly where the Maya meet the Lenca. Despite this important contribution by Longyear, this question has since been considered by Doris Z. Stone (1959), J. Eric S. Thompson (1970), E. Wyllys Andrews V (1977), and John S. Henderson (1978).

Only three titles were published in the series, presumably because of the disruption to the CIW research program caused by World War II. The number of each publication is unknown, although a search of *WorldCat*, an electronic bibliographic database, indicates that twenty-six copies are known to exist in libraries for no. 1, fourteen for no. 2, and eleven for no. 3. Complete sets are found in several major library collections, including the libraries at Bowdoin College, Harvard University, Newberry Library, University of Colorado, University of Pennsylvania, Yale University, and the University of Alberta in Canada.

THE CARNEGIE MAYA IV

General Preface

J. Eric S. Thompson

Clearly the time for attempting a complete synthesis of Middle American cultures has not yet arrived, yet our thoughts should be turning in the direction of that final objective. Data now coming to light in increasing quantities can in some cases be utilized to interpret phases of cultural history; in other cases they merely add to the great pile of unrelated items of information as yet not adapted to the general picture. It might be argued that these unfitted facts are best set to one side until fuller information is available, and that when the time comes to write the story of these early cultures, these unjoined pieces will fall into their places and produce the final picture. That would, of course, be the obvious procedure were the reconstruction of history truly comparable to a jigsaw puzzle; but in a finished jigsaw puzzle every piece has its place, and the whole forms a complete picture. Archaeology can never hope for such perfection either in the fitting of the pieces or in the integration of the final scene, and it is therefore necessary to give some thought to the interpretation of data as it becomes available, principally in order to obtain guidance as to what avenues might best repay exploration.

Some general objectives of research are already delineated in our minds, but few solid steps toward their interpretation have yet been taken. Rather than await fuller data casually amassed, it would seem preferable to outline tentative solutions which conform to information now on hand, with the purpose not of supplying final answers but of stimulating interest in these problems.

Under ordinary circumstances such reconstructions are particularly dangerous to the reputations of those that make them. Data that subsequently come to light may bring down the whole flimsy edifice of half-proved facts and unsubstantiated theories, with the result that the archaeologist is tempted to play safe by not indulging in speculation. Nevertheless, the moral of the wise old owl, although doubtlessly of excellent value for children, is hardly applicable to our discipline. Progress in our field is largely through trial and error. A reconstruction which fits the facts as now known, meager though they be, can be extremely useful, even if largely incorrect. It stimulates others in the field to watch for further data in connection with every component element, and leads them to seek confirmation or refutation of every idea advanced. Few ideas in recent years have kindled greater interest or led to more independent thinking than that of the Q-complex, advanced by Lothrop and Vaillant. Even should every scrap of that outline prove to be false, its publication would still be more than justified by the new orientation of our thought it has produced. Speculation presented as substantiated fact has, of course, no place in an archaeological report, but it is high time a place were provided for it, with the proviso that it be plainly indicated as such.

This series offers a platform for such reconstructions and they are so clearly labeled as tentative that their authors will not be called on to stand by the ideas they advance or be expected to spend the rest of their days defending themselves against the

charge of rashness, unreasonably classed by most archaeologists as the most heinous offense in our discipline.

Papers printed in this series may later be reissued in modified form as a result of the flow of information that will, it is hoped, be stimulated by their publication. The series will also be open, as far as funds permit, to papers advancing evidence for or against ideas, general or specific, already published. In short, it is hoped to make of the series a forum, in which historical reconstructions will grandly evolve

from the hypothetical to factual in order to prepare the way for the final synthesis of Middle American cultural history.

Perhaps not of least importance, this series may serve as a counterbalance to overspecialization in single and distressingly narrow fields, for although we of the present generation collectively have fuller information at our disposal, yet individually we lack that broad comprehension of the field possessed by our predecessors, particularly those grand writers of nineteenth-century Mexico.

Dating of Certain Inscriptions of Non-Maya Origin

OUTLINE OF THE PROBLEM

Recently there have been brought to light in southern Veracruz several stelae which utilize in peculiar fashion glyphs with numerical coefficients, and

numbers, expressed by bars and dots but unattached to glyphs. Their discovery has raised a number of chronological problems but, at the same time, has sensibly augmented data for segregating inscriptions that do not conform to the Maya patterns of date recording.

The aims of this paper are:

1. To separate these unorthodox inscriptions into two groups, Maya and presumably non-Maya.
2. To show that all inscriptions of the second group are related in method of epigraphic presentation.
3. To produce evidence indicating that one of the monuments of the second group is late, and thereby cast doubt on the antiquity of the whole group.
4. To outline cultural connections between the two areas (southern Veracruz and Pacific slope of Guatemala) in which monuments of Group 2 are found, and to present data tending to date the period of most intensive contact as approximately A.D. 1200 principally through comparisons with the well-defined and reasonably well-dated Mexican period at Chichen Itza and with the aid of certain artifacts that can also be dated with some assurance.
5. To suggest that present data can best be interpreted by assigning the monuments of Group 2 to the same cultural influences that were strongest about A.D. 1200.

Much of the second part of this paper, in which the fourth aim is discussed, is a theoretical construction, recognizably weak and primarily set up to be shot at by others in the field. It represents a re-employment of the methods and approach of the nineteenth century historian in combination with a utilization of the results of excavations of recent years. This method has been brilliantly pioneered by George C. Vaillant (1927), particularly in his paper "A Correlation of Archaeological and Historical Sequences in the Valley of Mexico." The present writer has, like many an imitator before him, wandered onto even more unstable ground, in this case with the additional, if somewhat doubtful, aid of an ethnological crutch.

EPIGRAPHIC DATA

GLYPH LESS NUMERICAL COEFFICIENTS ON MAYA INSCRIPTIONS

There are four known occurrences in inscriptions of indubitably Maya origin of numerical bars and dots unattached to glyphs. These are at El Pestac, Palenque, Menche (Yaxchilan), and in the Dresden Codex.

The Pestac stela (Blom 1929:10) has an Initial Series introducing glyph of normal form, followed

by 9, 11, 12, 9, and 0. The numbers are expressed by perfectly clear bars and dots, the zero by its normal Maya sign. There follow an eroded glyph, presumably the day sign, and a glyph with coefficient of 7 or 8. Since the Initial Series 9.11.12.9.0 reaches 1 Ahau 8 Cumhu, there can be little doubt that this second glyph is the month sign 8 Cumhu. Morley (1:132) considers the zero sign to be an effaced uinal glyph, and opts for 9.11.12.9.6 7 Cimi 14 Cumhu, apparently unaware of Blom's decipherment, which is that given above and which is without the slightest doubt the correct one. Glyphs on the back of the stela are in pure Maya style, certainly not early or very late, and are in agreement with acceptance of the Initial Series as the approximate date of the stela's erection.

On the hieroglyphic stairway at Palenque there is an apparent Secondary Series of 11.11.13 expressed by bars and dots unattached to period glyphs and enclosed in a cartouche, somewhat reminiscent of that on Stela 49, Menche, next to be discussed. This supposed Secondary Series lies between Calendar Round dates, but does not connect them, so far as one can tell from the rather eroded condition of this part of the inscription. The Initial Series and a Calendar Round date record 9.8.9.13.0 and 9.9.2.4.8, both of which are important dates recorded on other monuments falling in the period 9.10.10.0.0 to 9.13.0.0.0. There can, therefore, be little doubt that this inscription also dates from about 9.11.0.0.0. The style of the glyphs is in general agreement with this position.

On Lintel 49, Menche (Morley 1937-1938, 2:377), there is a series of bars and dots unaccompanied by glyphs within a sort of a cartouche forming one glyph block. This lintel is datable as not earlier than 9.4.10.0.0 and, on stylistic grounds, not later than 9.8.0.0.0. Morley's suggested position of 9.5.0.0.0 seems by far the most likely, but that it represents an Initial Series, as Morley supposes, is a different matter. Morley compares this series to the majority of Initial Series of the Dresden Codex on the grounds that both lack period glyphs and Initial Series introducing glyphs. That is true, but the important point is that in every case the terminal dates of these series in the Dresden Codex are given, whereas the series on Lintel 49 has no ending day. Furthermore, in every case in which the Initial Series introducing glyph is lacking in the Dresden Codex, the starting point is indicated, and in many cases this is not 4 Ahau 8 Cumhu. These series then are strictly speaking not Initial Series at all, since the term Initial Series is definable as a count from a fixed starting point in the past, which from usage had become so well established that it could be suppressed. The so-called Initial Series in the Dresden Codex which

lack introductory glyphs are in fact Secondary Series uniting varying starting points, always identified by day sign or Calendar Round date, to positions also expressed by day sign or Calendar Round date. They are, therefore, hardly to be compared to the series on Lintel 49, which, if it has a numerical meaning, must be a Secondary Series, similar to that of the Palenque inscription.

The Dresden Codex, in which, as noted above, period glyphs are suppressed, is of unknown date. The present copy probably dates from not earlier than A.D. 1100, and is certainly post-stela. Whether in an earlier original period glyphs were frequently suppressed naturally is a question that cannot be answered.

So far then as definitely Maya inscriptions are concerned, period glyphs were rarely suppressed on monuments of the Old Empire, but three cases being known. Two of these are probably Secondary Series, the third is an Initial Series. But this last has the introductory glyph and both day and month positions given, and there is strong evidence that the count was from 4 Ahau 8 Cumhu, both because of the form of the variable element in the introductory glyph and because the coefficient of the eroded month sign almost certainly requires a counting point with month coefficient of 8.

In the case of the Dresden Codex, starting and terminating points of periodless series are given without exception.

The rare examples in the Old Empire date from perhaps as early as 9.5.0.0.0, certainly not much later, to about 9.12.0.0.0. All are in the State of Chiapas.

GLYPH LESS NUMERICAL COEFFICIENTS ON SUPPOSEDLY NON-MAYA INSCRIPTIONS

Numerical bars and dots unattached to glyphs have been reported from two areas outside that of Maya culture; southern Veracruz and the Pacific slope of the Guatemalan highlands. They also occur in three Mexican codices, which are assigned by all authorities to southern Mexico. Unfortunately not one of these inscriptions is both complete and unequivocal. The best preserved is the Tuxtla statuette, followed by Monument 1, El Baul, Guatemala, and stelae from Cerro de las Mesas, Tres Zapotes, and Alvarado, all in southern Veracruz, in descending order of preservation.

The Tuxtla Statuette

It is now popularly assumed that the bars and dots incised on the Tuxtla statuette have been correctly deciphered as an Initial Series of Maya type, forming a time count of 8.6.2.4.17, leading from the

Maya base 4 Ahau 8 Cumhu to 8 Caban and a suppressed 0 Kankin. However, at the time the statuette was first described, such was not the case. C. P. Bowditch (Holmes 1907) wrote of it, "I doubt, however, if the inscription is clear enough to make it possible, in the absence of the month glyph, to determine with certainty what this date is, or, indeed, whether it takes the place of an Initial Series in the inscriptions." At the same time he was not satisfied that the katun coefficient was surely six, or the cycle coefficient eight. At a later date (1910:122) he reiterated his scepticism. Eduard Seler (1902–1923, 3:682) even doubted the authenticity of the inscription. Morley (Holmes 1907:698) also expressed doubts concerning the coefficients queried by Bowditch, but concluded "the best reading would seem to be 8.6.2.4.17." Recently (Morley and Morley 1939:8) he has accepted the above reading without question, but lists objections which lead him to consider that the object itself may be of considerably later date.

Morley's identification of the glyph at the head of the inscription as the Initial Series introducing glyph was largely instrumental in leading to a general acceptance of the proposed reading. Nevertheless this identification is open to serious question, for a close examination of the glyph reveals that the lower part is formed by two bars, the numerical value of which is shown by the projection of their ends beyond the sides of the glyph above them (Fig. 1.1a). In Maya inscriptions numerical bars never project beyond the limits of the glyph (in the case of a Secondary Series, beyond the glyph and coefficient when more than one) to which they are attached, nor are they ever below the glyph, with the solitary exception of Glyph A of the lunar series.

A comparison of this glyph with others from non-Maya inscriptions in Mexico reveals definite resemblances not only in the glyphs themselves, and in the numerical bars with regard to position and projection beyond the limits of the glyph above, but also in the presence of triple elements of a spiral form in the superfix, the element which led Morley to identify the whole as the introducing glyph (Fig. 1.1a).

Actually, this supposed introducing glyph bears a quite marked resemblance to the Zapotec Glyph D (Fig. 1.1b, c; Caso 1928, Fig. 7) which Caso in turn relates to the Mexican glyph for water (Fig. 1.1d–i). This latter frequently takes the form of a wide-mouthed dish containing water, which is represented, as is the usual Mexican manner in picturing liquids, by curves and spirals (frequently terminating in circles or ovals, perhaps shells) rising from its surface. There is also some resemblance to the glyphs for reed and flower.

1.1. Various glyphs: *a*. so-called Initial Series introductory glyph of the Tuxtla statuette (drawn from the original); *b*, *c*. Zapotec Glyph D (after Caso 1928); *d*–*h*. day sign Atl (various codices); *i*. Zapotec glyph in Tomb 105, Monte Alban, Oaxaca (after Caso 1938); *j*. glyph at Xochicalco, Morelos (after Seler 1902–1923); *k*. Zapotecoid glyph in Temple of the Jaguars, Chichen Itza, Yucatan (after Maudslay 1889–1902).

The resemblances are certainly much stronger to Mexican glyphs than to the Maya Initial Series introducing glyph. Indeed, were it not for its position at the start of a series of bars and dots, there would be no reason to make the latter identification. The central element also recurs in a compound glyph on the (observer's) left side of the statuette.

If, as seems very probable, this is a non-Maya glyph with coefficient of 10, clearly the inscription is not Maya. We shall find other cases of presumably non-Maya inscriptions of possible Initial Series form in which a glyph with coefficient stands above the bars and dots. The only parallel to this arrangement of bars and dots lying between day signs is the so-called Initial Series of the Dresden Codex. It is, therefore, plausible that the bars and dots on the Tuxtla statuette connect the date at the head of the inscription with that at the bottom. Other reasons for doubting the Maya origin of this statuette are its style, which will be discussed later, and its provenience, San Andres Tuxtla being west of any known Maya site.

Also the supposed terminal date of the Initial Series, with coefficient of eight, so far as one can

make it out, is unlike any Maya day sign, least of all like Caban, the day sign required for an Initial Series 8.6.2.4.17 of Maya type. The glyph has a superfix, a detail found with no Maya day sign, but just conceivably the "centipede" element found with some early but also with some late (Thompson 1937:191) Maya inscriptions.

Of the hieroglyphic inscription on the Tuxtla statuette it can, therefore, be said:

1. In all probability it opens not with a Maya Initial Series introducing glyph, but with a non-Maya glyph with coefficient of 10, expressed by two bars beneath, a method frequently used outside the Maya area but never with a Maya day sign.
2. The terminal glyph has features which suggest that it is not Maya. Since, therefore, the only two glyphs on the front probably are not Maya, it is very doubtful that the inscription itself is Maya. Glyphs on the sides might be Zapotecoid or very crude Maya.
3. The bars and dots probably have been correctly identified but their numerical values are not certain.

4. Even if the bars and dots represent an Initial Series, there is no evidence that the count is from the Maya base, 4 Ahau 8 Cumhu, and in view of a possible day sign at the start of the inscription, it is more probable that that represents the starting point, as, for example, in the so-called Initial Series in the Dresden Codex.
5. Even should the bars and dots represent an Initial Series of Maya style, there is no evidence that the date expressed was present time when the jade was carved.

Monument 1, El Baul

This stela from a small site not far from Santa Lucia Cozumahualpa, on the Pacific slope of the Guatemalan highlands, was discovered some years ago and examined by T. T. Waterman (1924) and R. Burkitt (1933). On the left side of the front a day sign 12 Malinalli, accompanied by two indecipherable glyphs, is followed by a series of bars and dots unaccompanied by glyphs. To the right the inscription continues with a double column of totally eroded glyphs. In 1928 Walter Lehmann submitted to the 23d International Congress of Americanists in session at New York a decipherment of the inscription, which he claimed recorded an Initial Series 7.19.7.8.12 12 Malinalli (or Eb; the Maya equivalent), and that this was the date of the erection of the monument, thereby making it the earliest contemporaneously dated stela then known in Central America. Lehmann's paper was not published in the proceedings of the congress, perhaps because of the lively scepticism his views had evoked. Morley (1937–1938, 1:132) accepts Lehmann's reading, but rejects the date as being that of the erection of the monument. Waterman (1929) produces evidence that the monument is of late date, and assigns it to the Aztec.

Actually, Lehmann's reading is open to very serious question. A close examination of the supposed katun coefficient, the right side of which is missing (Waterman 1924, Fig. 5; Burkitt 1933, Fig. 4), reveals that there is not room above the three bars for the four dots necessary to make this number 19. A reading of 18 for this number is preferable, for were there two dots to the right of the two now remaining, equally spaced and of equal size, the circumference of the right-hand dot would pass beyond the edge of the glyph panel. It is also true that only three dots would not produce a symmetrical coefficient, but a photograph in my possession seems to show the surface to the right of the second dot not flaked off and with no sign of a dot on it. Had there been four dots in this row, the two on the right would I have been so squeezed that the left edge of the third

must have been touching the right edge of the second, but, to judge by the photograph, such was not the case. Morley's (1937–1938:1, Fig. 3) drawing shows a break immediately to the right of the second dot. This drawing, however, is clearly made from Waterman's illustration, for the parts of the design covered in the latter's photograph by an arm and a leg of two persons posed beside the monument are shown blank in Morley's drawing. However, Morley supplies details of the numerical bars and dots not visible in Waterman's or Burkitt's photographs or that in my possession.

As the supposed tun coefficient is entirely, eroded, Lehmann's identification of it as seven is purely a guess. Actually, the space between the supposed katun and uinal coefficients calls for not one bar and two dots, as Lehmann assumes and Morley draws, but for two bars and an unknown number of dots, i.e., a coefficient of 11 to 15 inclusive.

The uinal coefficient is seven or eight with no way of saying which is correct because of flaking.

The supposed kin coefficient is also badly eroded, and Lehmann's reading of it as 12 is due to his wish to make this conform with the day sign on the assumption that the count is from 4 Ahau 8 Cumhu. Furthermore, in Burkitt's photograph, taken when the monument was better preserved than it is now is, the first two numbers occupy a trifle less than half the length of the inscription, and therefore there is not room for the rest of Lehmann's reconstruction for that would require more than one and a third times the space filled by the first two numerical blocks.

The whole reading is clearly so farfetched that it was not worth publishing as a possibility. The inscription is too badly flaked to yield any decipherment that has more than one chance in twenty of being correct.

Waterman (1924:11) has called attention to the resemblance of the glyph at the head of the inscription (Fig. 1.2a) to the Aztec day sign Malinalli. Morley points out that Eb, the Maya day sign equivalent to Malinalli, also carries a jawbone, and, therefore, the day sign might conceivably be Eb. However, Eb is more usually a human skull in profile, and always seems to incorporate a Cauac element, even in the case of the Leiden plaque, where a jawbone replaces the skull (Fig. 1.2h). In most Mexican representations of the corresponding Malinalli a grass symbol is incorporated in the glyph.

There is, however, one detail that strongly supports a non-Maya and, at the same time, a non-Aztec origin for this day sign, and which hitherto has escaped attention. In Mexican codices of non-Aztec origin, jawbones, whether forming parts of skulls

1.2. Examples of day signs Malinalli and Eb and Jawbones: *a*. Malinalli, Monument 1, El Baul, Escuintla; *b*. Malinalli, Codex Laud; *c*. painted jawbone on vessel from Isla de Sacrificios, Veracruz (after Joyce 1912, 1914); *d*–*g*. examples of Maya sculptured jawbones; *h*, *i*. Eb, Leiden Plate and Lintel 12, Piedras Negras, Guatemala; *j*. Aztec form of Malinalli.

or representing the day sign Malinalli are very frequently equipped with serrated protrusions along the under side (Fig. 1.2b; Seler 1902–1923, 1:834). The same feature is seen on a plate from Isla de Sacrificios, Veracruz, of Cerro Montoso phase (Fig. 1.2c). In Maya Old Empire art these protuberances are absent or are replaced by slight indentations (Fig. 1.2d–g). In codices known to have originated in the vicinity of the Valley of Mexico, such as the Codices Borbonicus, Telleriano-Remensis, and Magliabecchi, and the Tonalamatl of the Aubin collection, the Malinalli glyph has become a fearsome death's head in profile and in no way resembles the glyph at El Baul (Fig. 1.2j). To this group also belong the Malinalli glyphs of Codex Porfirio Diaz, which is of conquest times, although perhaps of Cuicatec origin. In post-conquest pictures, such as the Sahagun and Duran illustrations, the grass element has become a naturalistic plant.

On the other hand, Malinalli signs in Codices Laud, Vindobonensis, Bologna, Zouche, and Fejervary-Mayer (Fig. 1.2b), all of which are not Aztec but from southern Mexico, are the closest in delineation to the Malinalli glyph of the monument from El Baul. It is of importance in this connection to bear in mind that in three of these five codices numerical bars and dots are found. There can accordingly be no doubt that this glyph on the El Baul stela is neither Maya nor Aztec, but is most closely related to Malinalli glyphs of codices from southern Mexico. Glyphs of this southern Mexican group of codices will hereafter be referred to as of the Laud type.

Of the El Baul stela it may therefore be said that the possible Initial Series cannot be deciphered with any assurance because of its damaged condition. As

probably in the case of the Tuxtla statuette, it stands between glyphs, and does not start the inscription, and the preceding day sign is not Maya but closest to Laud-type examples of Malinalli found in codices from southern Mexico which probably were executed not long before the Spanish conquest. As in the case of the Tuxtla statuette, there are no grounds for believing the count was from 4 Ahau 8 Cumhu. Indeed, the neighboring Cakchiquel did not use that base. There is, therefore, no evidence for concluding that the stela is Maya.

Cerro de las Mesas

Fourteen years ago Dr. Herbert J. Spinden (1927) reported the existence of stelae at Cerro de las Mesas, a large group of ruins west of Alvarado in southern Veracruz, and noted the presence of numerical bars and dots on some of them. In 1940 these ruins were visited by Dr. Matthew Stirling; who, in a paper given in Mexico City in the spring of that year, read one of the inscriptions as an Initial Series of Maya type recording 9.1.12.14.10 1 Oc. Dr. Stirling has kindly placed at my disposal photographs of this text which are clearer than the one already published (Stirling 1940a:322; for drawing of this stela see Spinden 1927). As in the case of the El Baul monument and probably the Tuxtla statuette, the bars and dots, is unattached to glyphs, lie between signs, for the inscription starts with several obliterated glyphs. Then come the bars and dots without accompanying glyphs and, below, the inscription closes with a single sign, the head of an animal. Above this head is a dot which Stirling reads as one, thereby reaching agreement with an Initial Series of 9.1.12.14.10, leading from 4 Ahau 8 Cumhu. Below the glyph is an element which might

be the "tail-like" element which protrudes from the mouth of Oc in Maya inscriptions, but which might also be a numerical bar.

The glyph itself appears at first to be an animal head in profile, like the Maya Oc, but there is an eroded part to the left which might convert it into a full-face representation of a jaguar or some other animal or bird. If this left part is considered to have been plain, the glyph occupies only two-thirds of the glyph block, a decidedly unusual and asymmetrical arrangement. The bars and dots are far from clear. The coefficient of the supposed cycle period is very indistinct. It might well be 10. There are obliterated elements above it which might be more bars and dots or, perhaps, glyphs. The dot assumed to be the coefficient of the day sign at the bottom touches the bar above it, instead of being separated by the regular space. This raises two further possibilities. It might belong with the bars to which it is joined, making a coefficient of 11 or, since it has an ornamented center, it might be an ornament on the animal's forehead. While the Stirling reading cannot be rejected offhand, it cannot be classed as more than a possibility.

All one can say is that as in the case of the Tuxtla statuette no month sign follows the supposed day sign, and the bars and dots are between glyphs.

Spinden has called my attention to a stela in the Mexican National Museum which carries a number of glyphs which very definitely are not Maya (Lehmann 1921, Fig. 30). In subject matter and style these two monuments resemble each other so extremely closely that there can be no doubt that they were made at approximately the same time and place, but since the Lehmann stela is clearly not Maya, the inscription on Stirling's twin monument obviously must also be of non-Maya type. Lehmann notes that the stela he publishes was said to have come from Cahpultepec, a locality I have been unable to identify.

Stela C, Tres Zapotes

Stela C, Tres Zapotes, is from a site in southern Veracruz not far from either San Andres Tuxtla, the provenience of the Tuxtla statuette, or Cerro de las Mesas. Unfortunately the top part of the monument is missing and to reach the suggested reading of 7.16.6.16.18 6 Ezab one must assume that the count is from 4 Ahau, that there was a coefficient of seven on the missing top piece and that the supposed coefficient of the katun is 16, not 15 (Stirling 1940). Again the bars and dots are followed by what is presumably a day sign, but this is the last glyph of this fragment and it is therefore impossible to say whether any month position was ever recorded on this mon-

ument. The day sign, because of its peculiar elaboration, resembles no known glyph Maya or Mexican.

Stela 1, Alvarado

This monument (Batres 1905), now in the Mexican National Museum, seems to carry a number of bars and dots some apparently attached, others unattached, to glyphs. At or near, the head of the inscription is a sign within a cartouche, and at the close a coefficient of 11 is beneath a glyph. The inscription is of value because it is from the same general region as all of those under discussion, with the exception of the stela from El Baul, and seems to conform to the general pattern of these tests in presenting bars and dots between glyphs.

Stela 1, Piedra Labrada

This shaft has at the top a glyph within a cartouche, and underneath a coefficient of seven, expressed by a bar and two dots (Blom and LaFarge 1926, Fig. 38). The glyph has a superfix which is vaguely reminiscent of that of the day sign beneath the inscription on the Tuxtla statuette, and which, together with the position of the coefficient; definitely precludes the possibility that we are dealing with a Maya day sign. Caso (1937) has called attention to the resemblance of this glyph to others found on pottery of Teotihuacan.

THE 400-DAY YEAR

Before discussing further the above group of inscriptions, I wish to draw attention to another possible manner of recording time. We have seen that there are grounds for believing that these counts by means of bars and dots may not have been made from the fixed Maya base 4 Ahau 8 Cumhu, but from varying points of departure, and it has been noted that all the decipherable day signs on these monuments are non-Maya. Such being the case, there seem to be no grounds for accepting without question the assumption that the count is one of turns of 360 days and their multiples, since there is no evidence that a 360-day count was used by any people other than the lowland Maya.

We know that the Cakchiquel reckoned in years of 400 days and in 20-year periods of 8000 days. The Cakchiquel certainly did not borrow this 400-day count from the lowland Maya. Accordingly, if they themselves were not its inventors, they quite probably adopted it from their neighbors, the Pipil. This is not an unreasonable assumption since a number of the Cakchiquel month names are of Mexican origin, and the Pipil, as we shall see, certainly migrated to Guatemala from southern Mexican regions.

1.3. Derivation of Pipil glyph: *a*. glyph on Monument 1, El Castillo, Escuintla; *b*. headdress of figure at El Castillo, Escuintla.

In view of a possible southern Veracruz origin for this 400-day count, it is of interest to note that it works perfectly when applied to the Tuxtla statuette, if the first glyph has been correctly identified as a day sign with coefficient of 10 and is to be taken as the starting point of the count. The interval then would be 1, 328, 897 days (i.e., $160,000 \times 8$; 8000×6 ; 400×2 ; 20×4 ; and 1×17). Dividing this number by 13 for the 1–13 cycle of day coefficients, there is a remainder of 11. Adding this to the coefficient of 10 at the start of the inscription, a coefficient of eight is reached ($10+11=21-13=8$), and this is precisely the number attached to the day sign at the bottom of the series of bars and dots.

Unfortunately, none of the remaining inscriptions of this group is sufficiently well preserved to serve as a test of this system, but the fact that it works in the case of the Tuxtla statuette may be significant since in the case of pure chance the odds against reaching the correct coefficient would be 12 to 1.

STARTING POINTS OF COUNTS

If the Tuxtla statuette is counted from a day with a coefficient of 10, the El Baul monument from a day 12 Malinalli, and the Cerro de las Mesas stela from

some other point, it is obvious that we may be dealing with inscriptions without fixed bases of departure and that the starting points were chosen perhaps for their astronomical importance and reached by backward calculation from current time, as presumably were such dates as the 9 Kan 12 Kayab and the Ring Numbers of the Dresden Codex. Even among Maya-speaking peoples the base 4 Ahau 8 Cumhu was not the only starting point, for the Cakchiquel count started from a day 11 Ah (equivalent to 11 Ben of the Yucatecan calendar), whereas in Mexico there were, it would seem, various points of departure.

USE OF BARS AND DOTS AND NON-MAYA GLYPHS IN SOUTHERN GUATEMALA

A feature of this supposedly non-Maya group of inscriptions is the use of bars and dots with what one may assume to be day signs. Sometimes these are placed above, sometimes below or to the left of the glyph.

On Monument 1 at El Baul we have seen that the coefficient of Malinalli was expressed by two bars and two dots. It has been claimed that no other monument in this region resembles it, the implication being that this monument is of great antiquity,

1.4. Day sign Ollin: *a.* Monument 6, El Baul, Escuintla; *b.* Monument 15, Santa Lucia Cozumahualpa, Escuintla; *c.* south Mexican codex.

whereas the other sculptures from this and neighboring sites in the Department of Escuintla are very much more recent, and *inter alia* do not employ bars and dots (Stirling 1940:13).

At El Castillo, a site near El Baul, Stela 1 (see Appendix 3 for nomenclature of monuments in this area) carries a sequence of numbers from five to ten inclusive. All are expressed by means of dots except the number eight which is shown as a bar and three dots (Burkitt 1933, Fig. 9). The dots except those forming the number 10 are carved. The group of nine dots have monkey heads or perhaps skulls in their interiors. The group of six dots have carvings which superficially resemble the Aztec day sign Acatl, but the same sign is on the headdress of the individual ascending the rope in this sculpture and serves as, a celestial symbol on Monument 5, Santa Lucia Cozumahualpa (Fig. 1.3). Burkitt reads these as a series of consecutive days, but to do so one must make this last the day Tochtli, which it certainly is not, and consider the element at the bottom of the rope to be the day sign Malinalli, an extremely questionable identification.

Monument 6, El Baul (Burkitt 1933, Figs. 1, 2), has at the top a cartouche-enclosed glyph which can hardly be anything but the day sign Ollin 'movement' (Fig. 1.4a). To the left is distinguishable the outline of a numerical bar. Beneath are four circular cartouches with sculptured interiors and with arrangement similar to the dots on Monument 1, El Castillo. The Ollin glyph is not Aztec, but of the simpler Laud type found in codices from southern Mexico (Fig. 1.4c), for Aztec forms of Ollin show an elaboration which sets them apart (Beyer 1921:29). A somewhat similar Ollin with coefficient of nine is

on Monument 15, Santa Lucia Cozumahualpa (Fig. 1.4b; Seler 1892:249).

Monument 2, at El Baul (Waterman 1924, Fig. 3), carries a human figure, in front of which is a non-Maya glyph within a cartouche, which is without doubt Mazatl 'deer,' as Waterman states. From the deer's neck hang two stick-like objects with clefts in their ends. These probably represent the legs and cloven hoofs of the deer (Fig. 1.5a). In Codex Bologna a leg with cloven hoof is generally attached to the neck of Mazatl (Fig. 1.5b) and in Codex Fejervary-Mayer, belonging to the Laud group, the leg with cloven hoof sometimes serves alone as Mazatl (Fig. 1.5c). In codices from the Valley of Mexico and that neighborhood this hoof is never an element in the day Mazatl. This glyph, therefore, serves to link once more the inscriptions of this region with those of southern Mexico, yet it should be noted that whereas in southern Veracruz the glyphs resemble more those of central south Mexico and the Zapotec writing of Oaxaca, those of the Pacific slope of Guatemala are very close to glyphs of the Laud type. It is also noteworthy that, as in several codices of the south Mexican group, dots alone as well as bars and dots are found on the same inscription to record numbers above four. Glyphs within circular cartouches are not only common on these sculptures of the Pacific slope of the Guatemalan highlands, but also occur in Codex Borgia, which is undoubtedly of south Mexican origin. They are also found on the jade statue of Quetzalcoatl in the Stuttgart Museum (Seler 1902-1923, 3:392) which, from the style of the sun shield and that of the glyphs themselves, must belong to the period almost immediately prior to the Spanish conquest.

1.5. Day sign Mazatl: *a*. legs and hoofs attached to deer head, Monument 2, El Baul, Escuintla; *b*. leg and hoof attached to deer head, Codex Bologna; *c*. Leg and hoof substituting for head, Codex Fejervary-Mayer.

USE OF BARS AND DOTS AND ZAPOTECOID GLYPHS IN MEXICO

Bars and dots are found beneath glyphs in most Zapotec inscriptions (Caso 1928), at Xochicalco (Seler 1902–1923, 2:138–67) in numbers, on a stone vessel said to be from the Chalcan territory (Seler 1902–1923, 2:161); on a monolith from Tenango (Seler 1902–1923, 2:159), and at Teotihuacan (Caso 1937). In addition, on the sculptures of Room E of the Temple of the Jaguar at Chichen Itza, which are without question of the Mexican period, is a glyph with a coefficient of eight beneath (Fig. 1.1k). All these glyphs are of Zapotecoid type, by which is meant glyphs of the same general type as those in Zapotec inscriptions, which would include those of the southern Veracruz group. On a column of the Temple of the Warriors, another building of the Mexican period at Chichen Itza, is what appears to be a rabbit's head with a coefficient of 10, expressed by two bars beneath (Morris, Charlot, and Morris 1931, Fig. 231) and throughout this complex as well as in the Castillo, another building of the Mexican period at Chichen Itza, are numerous name glyphs of non-Maya type. Only in the Northeast Colonnade (E. B. Ricketson) are there name glyphs which might be Maya. The glyph from Room E with coefficient of eight beneath is of particular interest since it is a sign found also at Xochicalco and

on the Chalcan stone box and Caso believes that it is probably related to the Zapotec Glyph A (Caso 1928, Fig. 3). Since the temple of Xochicalco has already been compared to the Temple of the Jaguar of the Chichen Itza ball court and the suggestion made that they are very closely related (Breton), we have some grounds for dating this glyph as about A.D. 1200, the approximate date of the ball court at Chichen Itza. The occurrence of a plaque of pure Xochicalco style in the Aztec deposits of the Calle Escalerillas (Batres 1902:24) strengthens the late date assigned to that style. Some of the glyphs at Xochicalco are of Zapotecoid style, others of the Laud type. For example, the Ollin glyph with a coefficient of two beneath (Seler 1902–1923, 2:140) is of Laud, not Aztec style. We can, therefore, be reasonably certain that a mingling of these two styles of glyphs had taken place by about A.D. 1200.

Glyphs with numbers below have been reported from Tajin (E. S. Spinden 1933, Pl. 17), on the rock of Maltrata (Batres 1905, Pl. 6) and the latter of both Zapotecoid and Mexican types, and, on a stone from Cuilapan, Oaxaca, of Mixtec origin (Caso 1928, Fig. 95). The absence of Nahuatl type glyphs on pottery of Teotihuacan III or late II may be significant in dating the diffusion of this epigraphic style. Bars and dots are found together with glyphs of Laud style in Codices Fejervary-Mayer, Bologna, and Laud.

POSSIBLE YEAR-BEARER GLYPHS ON ESCUINTLA MONUMENTS

The prominence of the days Ollin, Mazatl, and Malinalli on the Escuintla monuments raises the possibility that these were employed as year bearers in contrast to the regular Mexican custom of using Calli, Tochti, Acatl, and Tecpatl. The former set of year bearers, however, is found in Codices Porfirio Diaz and Fernandez Leal, believed to be of Cuicatec (N. Oaxaca) origin, and in Fragment 1 of the Humboldt collection, of unknown origin.

SUMMARY OF EPIGRAPHIC DATA

Bars and dots unattached to glyphs occur on only three monuments of indubitably Maya origin. Only on Stela 1, Pestac, do they form a clear Initial Series, and there they are preceded by the regular Maya Initial Series introductory glyph and terminate with a weathered day sign and what is almost certainly the corresponding month position of 8 Cumhu. The bars and dots on the hieroglyphic stairway at Palenque surely represent a Secondary Series. Those on Lintel 44 at Menche (Yaxchilan) might form an Initial Series, but there is absolutely no proof that they do since there is no introducing glyph and no day or month sign at the end of the sequence. It may be significant that all three inscriptions are from ruins in the western part of the Maya area, and consequently not far from the sites in southern Veracruz where the same custom obtains. It is, therefore, possible that they may represent borrowings of an alien trait.

The so-called Initial Series in the Dresden Codex, formed of bars and dots without the corresponding period glyphs, invariably record the days from which they are counted and to which they proceed. The corresponding month positions are usually given except in the case of bases of tables which were constructed to serve over and over again at various points in the Maya Long Count.

The Maya use of bars and dots without corresponding period glyphs extends from approximately 9.5.0.0.0. to 9.12.0.0.0. There is no evidence of this practice on very early monuments.

The inscriptions of southern Veracruz and El Baul are distinguished from the period less Maya texts by the fact that they appear to lie between two day signs, month positions are suppressed, glyphs are of non-Maya forms, and numerical coefficients may be beneath day signs. It is possible that the count was strictly vesigesimal, i.e., that the approximate year was of 400 days, as in the Cakchiquel calendar. It is probable that the bars and dots represent

the interval between the days between which they lie, and that no fixed counting point, such as the 4 Ahau 8 Cumhu of the Maya, was employed. In view of this probability it is evident that these series cannot at present be related chronologically to the Maya Initial Series system.

The glyphs on the monuments of southern Veracruz are Zapotecoid in form; those of the Pacific slope of the Guatemalan highlands are of Laud (south Mexican) style, but not Aztec. The mingling of these two types of glyphs occurs on the principal structure at Xochicalco, an admittedly late building; both styles continued their separate existences until the Mexican period at Chichen Itza, since at Chichen Itza glyphs of Zapotecoid type with bars and dots beneath occur on buildings of the Mexican period; glyphs of Laud (south Mexican) type in association with bars and dots are depicted on codices in use at the time of the conquest, and in one case (Bologna) apparently unfinished.

The evidence is not conclusive, but, so far as it goes, indicates that the various inscriptions of southern Veracruz are related to Monument 1, El Baul, and that in turn can be shown to have employed the same distinctive style of glyph, the Laud type, as the other monuments of the Pacific slope and therefore was probably of approximately the same period. The absence of Laud-type glyphs at Teotihuacan, but the presence of both Laud and Zapotecoid glyphs on the late structure at Xochicalco, and of Laud glyphs in codices in use at the time of the conquest, suggests that this style was flourishing at a comparatively late date. The use of bars and dots is no indication that an inscription is necessarily Maya or Zapotec.

STYLISTIC DATA

STYLISTIC AFFINITIES OF ESCUINTLA MONUMENTS

To clarify the extremely confused enumeration of bas relief monuments on the Pacific slope of the Guatemala highlands a new enumeration, largely based on that of Babel, is given in Appendix 1. We have seen that on many of these monuments there occur day signs of Laud type such as are found in codices which presumably do not long antedate the Spanish conquest, and it has been noted that both this type of glyph and the use of bars and dots are found on Monument 1, El Baul, as well as on other sculptures in this region. This would suggest that the former does not represent an entirely different horizon, as Stirling (1940:13) claims on the ground that no other monument in this area bears any resemblance to it. Actually, as we shall see, there is a very definite relationship.

1.6. Deities gazing from the heavens: *a*. Monument 1, El Baul, Escuintla (after Waterman 1929 and photographs); *b*. half of jaw of celestial monster, Monument 7, Santa Lucia Cozumahualpa, Escuintla; *c*. Temple of the Warriors, Chichen Itza, Yucatan (after Morris, Charlot, and Morris 1931); *d*. Acanceh, Yucatan (after Seler 1902–1923); *e*. Monument 5, Santa Lucia Cozumahualpa, Escuintla (after Habel 1878); *f*. Stone 1, National Museum of Mexico, Zapotec (after Caso 1928); *g*. from fresco at Mitla, Oaxaca (after Seler 1904a).

The subject most generally treated in these Escuintla sculptures is that of one or more supplicants who gaze up to, or climb toward, a deity placed at the top of the scene and represented by either the head and shoulders or the head only of a personage in an attitude of looking or falling down from the sky or the sun (Fig. 1.6e). To this group belong Monuments 2–8 and 15 at Santa Lucia Cozumahualpa, all of which represent ball-game players and may have formed part of the decoration of a ball court (Thompson, 1941), Monument 1 at El Castillo, and Monuments 1–3 at Palo Verde, although the sky to which the individuals in these last raise their hands is devoid of deities. Monument 1, El Baul, clearly belongs to this series since at the top a human head emerges from a celestial symbol (Fig. 1.6a). This last is, almost certainly a conventionalized representation of the upper jaw of a celestial monster. Monument 7, Santa Lucia Cozumahualpa, has at the top a deity descending or gazing down from the open jaws of a saurian monster, undoubtedly a celestial being. The volutes and treatment of the eye are very similar to that of the celestial monster on Monument 1, El Baul. A drawing of half of the former (Fig. 1.6b) illustrates the resemblance which would doubtlessly have been greater had the Santa Lucia monster's jaw also been shown in profile instead of being drawn to show the inside.

The concept of deities gazing down on worshippers from the sun, the sky, or the open jaws of a celestial monster is absent in the Old Empire with the possible exception of certain sculptures at Menche (Yaxchilan), falling between 9.11.0.0.0 and 9.17.0.0.0, which show the faces of gods looking down from Venus glyphs, which, in turn, are

pendent from celestial bands. On the other hand, this motif is extremely common in sculptures of the Mexican period at Chichen Itza, where the sections of sun disks bear a remarkable resemblance to those of Santa Lucia (Fig. 1.6c), in Mexican codices (Fig. 1.8d), and Zapotec stelae (Fig. 1.6f), and on frescoes at Mitla of the Mixtec period (Fig. 1.6g). The individual portrayed on Monument 1, El Baul, shares with almost all personages represented in Escuintla art the peculiar feature of a long headdress which reaches to the waist, although in the first case this is not as clear as it might have been because of flaking.

The head in the supposed jaw of the celestial monster on Monument 1, El Baul, is of a peculiar type. The nose is bulbous and from its end projects a round circle, presumably a bead worn as a nasal ornament, and the lips are extremely thick and protruding. The human head in the jaws of the *Xiuhcoatl* (celestial snake), which forms the headdress of the figure on Monument 2, El Baul, is of the same type. The same thick lips and bulbous nose with bead in front are present and the eyes are treated in the same manner.

These correspondences, when taken in conjunction with the head-in-sky motif, the use of bars and dots, and the employment of the same Laud type of glyph, surely show that there can be little doubt as to Monument 1, El Baul, belonging to the same general period as the other sculptures in this area.

The generous use of scrolls and curves, the treatment of the legs and, in fact, every feature which Stirling (1940:12) uses to set Monument 1, El Baul, apart from other sculptures of the region, are in reality shared by most of these sculptures, as an examination of the works of Habel, Seler (1892), Strebel (1901), and Figure 1.6b, e clearly shows. The

1.7. Volute decoration: *a*. Monument 1, El Baul, Escuintla; *b*. southern Veracruz element on Stela 6, Izapa, Chiapas; *c*. Stela 6, Izapa, Chiapas.

same style emphasizing scrolls occurs near Tonalá, Chiapas (Palacios), and particularly on monuments from Izapa, where there is a blending of Totonac and Pipil styles.

The dominant scene in the whole group of Escuintla sculptures, ball-game players, in all their ceremonial paraphernalia, rendering homage before or after the game, to celestial powers, in execution and in the elaboration of the subject matter hardly suggests an incipient stage of culture, even less so if the assumption that these sculptures formed decorative panels on a ball court be correct.

Another motif, the main subject of two monuments and a subsidiary subject on a third, is an eagle bending over a sacrificed person, and holding the newly removed head in his claw (Fig. 1.8a). As is well known, the Aztec and other peoples of Mexico considered the eagle to symbolize the sun. Persons to be sacrificed were called 'the eagle people'; and the hearts of sacrificial victims, which were offered to the sun, were called 'eagle tuna fruit.' This symbolism is entirely absent from Maya Old Empire art, from classical Teotihuacan, and, the writer believes, from the Zapotec periods at Monte Alban. There seem, therefore, good grounds for believing that the concept is not of great antiquity, and, therefore, these Pipil sculptures also can not be of great age. Actually, the concept appears at Chichen Itza in buildings of the Mexican period (Fig. 1.8b), is present in sculptures at Tajin believed to be of about the same date

(Fig. 1.8c), and is found in Mexican codices, particularly those of south Mexican origin (Fig. 1.8d).

Monuments 6 and 8, Santa Lucia Cozumahualpa, Monument 1, El Castillo, and Monument 2, El Baul, are brought together by the fact that the main personages on them have headdresses decorated with Xiuhcoatl, which, like their wearers, are depicted in profile. The colossal head at El Baul can be brought into this group, since across its forehead stretches what is surely a Xiuhcoatl (Fig. 1.9). Perhaps the most characteristic features of the Xiuhcoatl are the cone-shaped segments which form its body. In Mexican art the belly of the Xiuhcoatl is usually smoothed, whereas in Escuintla sculpture it is the same as the back. The cone-shaped segmentation of snakes is unknown in Maya Old Empire art, and does not appear to be represented in classical Teotihuacan or Monte Alban, but is frequent in Mexican codices, especially those from southern Mexico (Fig. 1.9) and is occasionally found in Aztec sculpture. The characteristic style therefore is yet another link between Escuintla sculpture and rather later Mexican art. During the Mexican period at Chichen Itza a headdress very similar to that of the small Xiuhcoatl is worn. The snake's body is segmented, but the conical or trapezoidal outline is replaced by small squares, of equal size, with a dot in the center (Maudslay 1889-1902:3, Pl. 35b).

From the above it is clear that there are good grounds for relating Monument 1, El Baul, to the rest

1.8. The Eagle Cult of the Sun: *a*. Monument 16, Santa Lucia Cozumahualpa, Escuintla (after Habel 1878); *b*. Temple of the Warriors, Chichen Itza, Yucatan (after Morris, Charlott, and Morris 1931); *c*. greater ball court, Tajin, Veracruz (after E. S. Spinden 1933); *d*. Codex Selden A, p. 12.

1.9. The Xiuhcoatl: *a*. Monument 2, El Baul, Escuintla; *b*. Monument 3, El Baul, Escuintla; *c*. Codex Nuttall.

of the sculptures of the Pacific coast of Guatemala in the so-called Pipil style, and these in turn to art styles of Mexico, particularly the southern part, and to the Mexican period at Chichen Itza, datable as between A.D. 1100 and A.D. 1450.

SCULPTURES OF KAMINALJUYU

A number of sculptured monuments and fragments have been reported from Finca Arevalo, a part of the large site now known as Kaminaljuyu. Two of these are of particular interest in connection with the present study.

Sculpture E (Lothrop 1926a, Fig. 47) may be an altar. The top (or front) carries a seated figure in profile facing two columns of glyphs. The side has two weathered glyphs with bar and dot coefficient above, the second being enclosed in a cartouche. On the strength of these glyphs and the design, Lothrop assigned the sculpture to the close of the Old Empire. However, the features of the individual are not Maya. The thick lips and bulbous retrousse nose are the same as those already noted as occurring at

El Baul. Furthermore, the seated person wears the same fringed loin-skirt (of leather?) and perhaps the same wide belt as the ball-game, players on the Santa Lucia Cotzumalhuapa sculptures. The two glyphs cannot be a Calendar Round date or an end of a katun or tun date, as Lothrop suggests, since the first glyph lacks a cartouche.

Instead of considering these glyphs as lowland Maya, the nearest site (Copan) with definitely Maya glyphs being nearly 100 miles distant in a straight line, it is surely preferable to assign them to the Pipil, for Santa Lucia Cozumalhuapa is only some 40 miles distant, and the individual is stylistically closer to Pipil than to Maya sculpture. However, as we shall see, in some important respects the sculpture of this site is most closely tied to that of southwestern Chiapas.

Mixco, close to which the Finca Arevalo ruins are situated, is a Pokoman settlement, but Ximenez (1929-1931, Bk. 1, Ch. 26) cites an old lawsuit brought by the town of San Pedro Sacatepequez against Mixco, in which it is stated that the Pokoman of Mixco had been crowded out of El Salvador shortly

before the Spanish conquest (by Pipil?) and had been given lands at Mixco by San Pedro, a Cakchiquel town. In view of the Indian attitude toward the soil, one can conclude only that Mixco was deserted country; otherwise it would not have been voluntarily yielded to the Pokoman. It is, therefore, possible that the Pipil wave once reached as far as Mixco but later receded.

RESEMBLANCES BETWEEN MONUMENTS OF SOUTHERN GUATEMALA AND SOUTHERN CHIAPAS

According to tradition, as noted under that heading, the Pipil migrated to the Pacific slopes of Guatemala and El Salvador from central and southern Chiapas. It is therefore logical to seek in the latter areas for origins of the distinctive style of the sculptures of Escuintla tentatively assigned to the Pipil.

There are two large sites in southern Chiapas. That near Tonalá, close to the border of Oaxaca, has been briefly explored by Palacios (1928:13–29) while Seler-Sachs (1900:111) reproduces one stela now in the main plaza of Tonalá. Izapa, near Tapachula, has been visited by Mr. and Mrs. Kidder and Mr. Ruppert, and photographs of monuments taken by them are in the, photographic files of the Division of Historical Research. In addition Burkitt (1924) describes briefly various sites in the vicinity of Tapachula.

A stela now in the railroad station of Tonalá (Palacios 1928, Fig. 24) is of peculiar interest. The main figure, of which the head is missing, represents a ball-game player. Like those of the Department of Escuintla, the personage wears a ball-game belt with grotesque, head in relief (Thompson 1941), has one hand encased in a glove, and wears an elaborate pad on one knee. Beneath is a glyph with coefficient of nine expressed by a bar and four dots. Unfortunately the glyph is completely weathered, but there seems no reason to suppose it is not of Zapotecoid or Laud type since the nearest Maya site with hieroglyphic inscription is far distant, and Tonalá is a long way outside the Maya linguistic area.

Other monuments include a pedestal statue belonging to a type discussed in the distribution of traits, and three huge flat boulders, as much as 3 m. long, which carry curvilinear designs and human or animal faces in low relief. The curvilinear designs are somewhat reminiscent of Totonac art, particularly in broken-down examples of the conch-in-cross-section motif, found also outside the Totonac area at Teotihuacan and Xochicalco. These huge altars of granite, however, strikingly resemble Sculpture D at Finca Arevalo (Lothrop 1926a, Fig. 47), now part of the Kaminaljuyu site, for they share with it the some-

what unusual form of a long, rather flat boulder, and in addition their intricate curvilinear designs in low relief are quite reminiscent of those of this monument at Finca Arevalo, while the subject matter in both cases appears to be the same double-headed celestial monster.

At Izapa several stelae carry designs in which closely rolled scrolls predominate. These again are analogous to those on monuments at Santa Lucía Cozumahualpa and particularly to those on Monument 1, El Baul (Fig. 1.7). The Izapa stelae have every appearance of lateness. In one case the scene seems to portray a Tlaloc, with water bag on his back, lifting a rain barrel. Below him is a two-headed serpent treated in a strongly Totonac manner (cf. E. S. Spinden 1933, Pl. 18c) whereas above him is a band with a simple geometric pattern which approximates closely that on the base of the Alvarado stela and that on the Tepetlaxco relief (Seler 1902–1923, 3:515). However, this pattern is so simple that its occurrence at Izapa may have no significance. The Burkitt photograph shows at the base of Monument 1, El Baul, an indistinct element which appears to be a double-headed serpent of the type of that just noted.

Another Izapa stela portrays a priest with bent sacrificial knife in his upraised hand similar to that on a fresco of the Temple of the Warriors at Chichen Itza (Morris, Charlott, and Morris 1931, Pl. 145), a building of the Mexican period. Of more interest, however, is the fact that the priest wears a skull of a type close to those represented in Escuintla art, which in turn resemble strongly skulls on flat stone heads both in southern Veracruz and on the Pacific slopes of Central America. Indeed, there is a strong predominance of the skull motif in Totonac, Olmec, and Pipil art, a geographical extension which can hardly be fortuitous. During the Mexican period at Chichen Itza there is a certain emphasis on death symbols, but in no way comparable to that on the Pacific coast. Skulls and death symbols are also extremely prevalent in Aztec art.

In the plaza of Tuxtla Chico is a statue of a jaguar in an upright posture, which has been moved thither from the nearby ruins of Izapa. Stylistically it is closely paralleled by a statue of a jaguar, also in the round, at El Baul (Richardson 1940, Pl. 19a).

Both Tonalá and Izapa, therefore, appear to be links between the cultures of southern Veracruz and the Pipil sites of the coastal slopes of Guatemala. They serve also to substantiate that central and southern Chiapas were the centers of the Pipil dispersal, and that the Pipil in their Chiapan homes had been exposed to influences from southern Veracruz as implied by the Olmec pressure said to have caused

1.10. Birds and birdmen: *a*. Tuxtla statuette (after Holmes 1907); *b–e*. pottery figures, southern Veracruz (after Batres 1908); *f*. pottery figure of volador performer (after Batres 1908).

the migration. Traditions confirming such migrations are cited under a heading to that effect.

STYLISTIC AFFINITIES OF THE TUXTLA STATUETTE

A number of years ago Lothrop (1921) called attention to the strong resemblance certain large stone sculptures in Nicaragua bore to the Tuxtla statuette: He proposed the stimulating thesis that these Nicaraguan sculptures and the Tuxtla statuette were both products of a Chorotegan culture which preceded that of the Maya. Lothrop wrote at a time when the antiquity of the statuette was unhesitatingly accepted, and his whole thesis was based on that premise. With the strong possibility, already demonstrated, that the Tuxtla statuette may not be an early Initial Series of Maya type, this theory must be examined anew.

A number of pottery figurines and whistles from southern Veracruz, particularly from the Rio Papaloapam-Tuxtla region in which the Tuxtla statuette was found, are in the form of birdmen similar to that on the front of the Tuxtla statuette (Fig. 1.10). Batres (1908, Pls. 12, 53, 56) and Valenzuela (1938, Fig. 3) illustrate examples in this style. This same general area is the chief center of a more evolved type of birdman which almost surely represents participants in the volador ceremony (Fig. 1.10). Distribution is noted in connection with the discussion of the volador ceremony, but attention is now drawn to the occurrence of this advanced type of birdman on a stone sculpture from the High Priest's Grave, a building of the Mexican period at Chichen Itza (E. H. Thompson 1938, Fig. 11). A pottery plaque from Coban, Alta Verapaz, to which Seler (1902–1923, 3:682) called attention a number of years ago, also resembles strongly the figure of the Tuxtla statuette, but this specimen, as well as the cruder type from southern Veracruz, can not at present be dated.

Into this group of billed figures fits a jade ornament found in Votive Cache 1 at Mountain Cow

(Thompson 1931, Pls. 31, 17 and 32, 34). This cache was dated as belonging to the local equivalent of Holmul V, but because of finding in it a cylindrical cache container of pottery and certain shell figurines, there is a possibility that this and other caches at Mountain Cow were assigned to a later place than their actual position (Thompson 1938:191–92). Actually, this particular cache is more firmly dated as late because it also contained a remarkable polished celt inscribed with glyphs, and there are some grounds for believing that polished celts are of late date in the Peten (Thompson 1940:128–29). A somewhat similar inscribed celt of polished jade was found at Kendall, British Honduras (Gann 1918, Pl. 16, Fig. 36). The glyphs of both celts are more Zapotecoid than Maya.

The pupils of the eyes of both the Tuxtla statuette and the amulet from Mountain Cow are rendered by small holes. Although this is an early feature, it survived until late times since it is typical of Zapotec funerary urns of the Monte Alban IV period, of late Maya incensarios, and of relief figures on plumbate pottery, and is not infrequent on Aztec sculpture.

It is also typical of pottery figures from the Rio Papaloapam-Tuxtla region, which because of their resemblances to late types from the mouth of the Usumacintla River, from the cenote at Chichen Itza, from the east coast of Quintana Roo, and from the latest horizon in northern British Honduras, must themselves be late. Of particular interest in connection with the stylistic placement of this amulet from Mountain Cow is the presence of a slight nick at the top of the head such as is found on votive axes of Olmec style believed to be of southern Veracruz origin (Saville 1929), and on Teotihuacan II and III pottery heads.

The style of the Tuxtla statuette can not at present, therefore, be used to place it in its chronological position, although we have hints that it is probably not earlier than the basal flanged-bowl horizon of the Peten-British Honduras area and may be considerably later.

STYLISTIC AFFINITIES OF STELA C, TRES ZAPOTES

The mask on the back of Stela C, Tres Zapotes, is the sole stylistic clue as to the date of this monument. It represents the conventionalized head of a jaguar and thereby is related to Olmec art. The treatment of the lips is Olmec in feeling although not as exaggerated as on the Olmec votive axes illustrated by Saville (1929). Unfortunately a similar treatment of the jaguar's snout occurs in Middle American art perhaps over a long period. It is certainly late, since, as Vaillant has pointed out, it occurs on a gold pectoral from the Totonac city of Papantla (Peñafiel 1890, Pl. 112), which is clearly contemporaneous with one found in Tomb 7 at Monte Alban, a Mixtec burial dating from just before the Spanish conquest (Caso 1932, Fig. 41). A jaguar muzzle rendered in truly Olmec style occurs on a yoke in the American Museum of Natural History, but, as we shall see, these can be shown to have been distributed on a late horizon, although they may have originated earlier. The Olmec jaguar style may have considerable antiquity, but since it endured until the arrival of the Spaniards its presence on a monument is no criterion of antiquity.

The treatment of the nose on the mask from Tres Zapotes parallels that of the Mountain Cow amulet already discussed, but exactly the same nose treatment is on a Tlaloc head from Uxmal (Seler 1917, Fig. 86), whereas the mask as a whole is as close to masks on columns of buildings of the Mexican period at Chichen Itza as it is to those on Structure E-VII sub at Uaxactun. Actually, representations of conventionalized jaguar heads are frequent in Maya art of the middle and great periods of Cycle 9, and in the discussion under the heading "The Olmec" it will be shown that many of these are much closer to the Olmec type in almost all their characteristics, particularly in the employment of the croquet-hoop form of the muzzle, than are the masks of the Uaxactun pyramid (Fig. 18; Dieseldorff 1926-1933:1, Figs. 175, 176; Joyce 1914, Fig. 65; Spinden 1913:17, Fig. 1). A jaguar deity is also depicted on Zapotec urns of Monte Alban II and III, and he, too, frequently has the croquet-hoop muzzle. In view of these long persistences it is clear that neither as a whole nor in its details can the mask of Stela C, Tres Zapotes, serve as a chronological clue.

STYLISTIC AFFINITIES OF STELA 1, CERRO DE LAS MESAS

Stela 1, together with the other stelae at Cerro de las Mesas, has been pronounced late on general stylistic grounds by Spinden (1927). The twin sculpture now in the Mexican National Museum (Lehmann

1921, Pl. 30) is of peculiar interest because the figure on it is almost certainly Quetzalcoatl-Eecatl, with his usual grotesque snout. Since Eecatl, complete with his snout, does not seem to have been recognized on any horizon definitely earlier than Monte Alban V (he is plainly represented on Mitla frescoes of that period), it is difficult to see how Spinden's conclusion can be challenged.

SUMMARY OF STYLISTIC DATA

There are good stylistic grounds for placing all Escuintla sculptures of the so-called Pipil culture late in Middle American history, probably between A.D. 1100 and A.D. 1450, because that was the period in which such features as gods looking down from heaven, the sun as eagle, and the Xiuhcoatl had their widest distributions. The stylistic affinities of the monuments with inscriptions from southern Veracruz are very much less certain. Some details are definitely late, but might also be early. The stela from Cerro de las Mesas does, however, have every indication of lateness.

DEDUCTIONS AND SURMISES FROM EPIGRAPHIC AND STYLISTIC DATA

All scenes portrayed on monuments from Santa Lucia Cozumahualpa, El Castillo, and Palo Verde are so closely related in subject matter or individual motifs and details of dress as well as in the type of epigraphic writing, that they must all be of approximately the same period. There is strong evidence for dating this period as approximately A.D. 1200-1450.

Monument 1, El Baul, can be brought into this dated group on the grounds that it, too, portrays a subject (a deity gazing down from the sky) very common on the other monuments, shares with them the use of glyphs of the Laud type, and, like two of them employs the bar and dot method of writing. Furthermore, the combination of bars and dots and Laud-type glyphs is commonest in the centuries immediately preceding the Spanish conquest.

The monuments in southern Veracruz under discussion are more difficult to place. The glyphs might be of any date, but the evidence of the sculptured scenes, although by no means conclusive, supports a late dating. There is nothing pointing to considerable antiquity to the exclusion of a much later stage. In fact, some of the subjects are known to have been dominant during the centuries immediately antecedent to the Spanish conquest.

The method of presenting epigraphic data on these east-coast monuments appears to be the same

as that on Monument 1, El Baul, and since there are good grounds for dating the latter as approximately A.D. 1200–1450, the period which best fits the stylistic evidence, the presence of this method of recording dates tends to support the suggested assignment to a late horizon.

Sculptured monuments in southern Chiapas are intermediate in style and space between these two areas. Treatment and subject matter indicate their erection on the same late horizon, whereas at Tonalá, one of these south Chiapan sites, a stela carries a glyph with coefficient expressed by the bar and dot method.

The evidence, then, suggests that in both southern Veracruz and on the Pacific slope of the Guatemalan highlands there existed between approximately A.D. 1200 and A.D. 1450 a non-Maya system of recording dates wherein what are presumably day signs are linked by series of numerical bars and dots functioning as a sort of Secondary Series with period glyphs unknown or suppressed. Southern Chiapas may have served as a transmitting point between these two cultural areas.

MIGRATION FROM SOUTHERN MEXICO TO THE PACIFIC COAST OF GUATEMALA

Evidence has been produced that the sculptures of the Department of Escuintla have much in common with an unidentified style of southern Mexico in general and southern Chiapas in particular, and the text of one monument has been compared to those found in southern Veracruz. Traditions of migration confirm the resemblances and help to date them.

Francisco Ximenez (1929–1931, Bk. 1, Ch. 26) wrote that every one from Escuintla to San Salvador and as far as Nicaragua was Mexican-speaking. Strictly, this was not an entirely true statement, but it is correct in so far as the vast majority of the inhabitants of the plains bordering on the Pacific from Escuintla to central Salvador were Mexican-speaking. Fuentes y Guzmán (1882–1883, Bk. 3, Ch. 2) similarly states that Pipil, a Mexican dialect, was spoken at Esquintepeque (i.e., Escuintla) and at some towns of the south coast beyond. Until late in the nineteenth century Pipil was still spoken around Escuintla (Stoll 1938:2).

As long ago as 1895 Seler (1904:112) derived the Pipil from the Tabasco regions and connected them with the Mexicans who imposed their culture on Chichén Itzá. He called attention to the tradition of the Pipil of Salama, a detached colony in the northern highlands of Guatemala, that their ancestors had come from Tuxtla Grande, and, like Stoll (1876:343), considered that this migration was in fact

pre-Columbian despite traditions that it was post-conquest. Seler (1902–1923, 3:628) identifies Tuxtla Grande with Los Tuxtlas, Veracruz, but there can be little doubt that it is Tuxtla, Chiapas, now known as Tuxtla Gutiérrez, the present capital of the State of Chiapas. Far to the south of Tuxtla Gutiérrez, there is a Tuxtla Chico near Tonalá; and Tuxtla, as the state capital, has always been more important than Los Tuxtlas to everyone except archaeologists.

Actually there exists a much earlier tradition of the migration of the Pipil. Torquemada (1723, Bk. 3, Ch. 40) recounts that the Indians of Nicaragua and those of Nicoya, also called Mangue, originally lived in Soconusco (southeastern part of the Isthmus of Tehuantepec). Those of Nicoya, who were of Cholulan descent, lived inland toward the Sierra; the Nicaragua, who were Mexicans from the land of Anahuac, lived toward the coast. Both were large groups. About seven or eight ages or lives of very old men (the kind who were taken out to sit in the sun because of their age) before the recording of the story these peoples were conquered by their old hereditary enemy, the Olmec, who had come from the direction of Mexico. The yoke of their Olmec oppressors was so severe that they migrated. The Nicaragua followed the Pacific coast across Guatemala, leaving behind certain groups who settled such places as Ezalcos (Izalcos, actually a Pipil settlement in El Salvador), Mictlán (the modern Asunción Mita), and Yzcuintlán (the modern Escuintla), and were then called the Pipil. The rest passed on to Nicaragua.

Both Stoll (1938:7) and Lothrop (1926:1:6) connect the life spans of the seven or eight aged men with the stay in Soconusco, but the Spanish text will not bear that interpretation. The period can refer only to the lapse of time between the arrival of the Olmec in Soconusco and the recounting of the tradition. One suspects that the ages, which are amplified by stating that they were the equivalents of very long life spans, actually represent 52-year cycles, the *Xiuhmopilli* of the Mexicans. If this tradition had been collected about 1550, as seems not improbable in view of the fact that Torquemada's history is almost entirely a compilation of earlier source materials, and the ages are 52-year periods, the Olmec, pressure which led to the migrations occurred somewhere between A.D. 1150 and A.D. 1200. The Olmec, according to Mexican historical sources were being pushed southward by the incursions of the Nononcalca-Chichimeca at precisely this time, and it is therefore not improbable that the settlement of the Pipil on the Pacific slope of Guatemala was an indirect result of the fall of Tula and the break-up of the Toltec-Nononcalca-Chichimeca hegemony.

Strangely enough, Torquemada's tradition implies that Olmec groups also migrated at the same time into Central America. There is some confirmation of the migrations of the Mangué and Nicaragua in linguistics, for Nicoya and Mangué are sub-families of the Chorotegan stock, to which belongs Chiapanec, spoken in the mountainous country of Soconusco, the legendary home of the Mangué, whereas Nahuatl is spoken on the coastal strip of Soconusco (Thomas and Swanton 1911:76; Mason 1940:80) from which the Mexican-speaking Nicaragua are said to have emigrated. This same tradition is recounted by García de Palacio (1860, Bk. 5, Ch. 5, *fide* Lothrop 1926:1:29) with the added information that all the Chorotega came from the direction of New Mexico, bringing with them two or three gods, and that in Soconusco they divided into two groups, one to settle in Nicaragua, the other the State of Chiapas. That the Nicaragua or Nicaraó, as they were more commonly called, were not Aztec is clear not only from Torquemada's account but also from the absence of the Aztec tribal deity Huitzilopochtli from their pantheon and the Aztec *tl* from their speech.

Remesal (1932, Bk. 5, Ch. 13) contradicts Torquemada and García, reporting an emigration from Nicaragua to the vicinity of the present-day Chiapa del Corso, the center of Chiapanec territory. This, however, in view of the distribution of the Otomanguéan stock (Johnson) is not likely, or, at most, would represent an ebb.

Motolinia (1914:9) mentions a migration by sea to Nicaragua from Mexico about a hundred years before the arrival of Cortés. The rather confused passage, in which Motolinia frankly states that part of what he writes is merely what he suspects to be the truth, might have reference to a later migration, or the four years of drought, which was its cause, may have been the same as that which accompanied the dispersal of the Toltec toward the close of the twelfth century. Migrations by sea crop up in Mexican legend, but it is hard to credit such seamanship to the ancient inhabitants of Mexico.

Torquemada's account of the Pipil-Nicaraó migration is most convincing because it mentions the Pipil settlements of Izalcos, Mitlan, and Escuintla, which check well with the facts, because the points of dispersal he mentions agree with linguistic evidence not at his disposal, and finally because this tradition is partly confirmed by García. Whether the Mangué migration took place at the same time is a more debatable matter.

The evidence, then, is rather strong that the Mexican-speaking people of Nicaragua believed that they had migrated in the twelfth or thirteenth

century from southern Chiapas, that some of their numbers had remained in Escuintla and western El Salvador, and that the migration was due to Olmec pressure. As we have seen, there is archaeological evidence supporting this tradition.

THE OLMEC

In recent years archaeological attention has been belatedly directed to the part of Veracruz state south of Veracruz City and the contiguous areas of Tabasco, Chiapas, and Oaxaca. Although but little excavation has been undertaken, enough is known of the archaeology of the area to permit the vague outlining of a culture to which on geographical grounds the name Olmec has been given tentatively and, one might add, almost furtively in the face of the present tendency to deprecate identification of archaeological remains with the sixteenth century inhabitants of the same area.

In her brilliant discussion of Totonac culture Ellen S. Spinden (1933:228, Note 8) has listed the authorities who accept with varying gusto the employment of the term Olmec to describe this culture, and she herself uses it in that sense.

Sahagún (1938, Bk. 10, Ch. 29) assigns the Olmec to the general region under discussion, but is vague as to the language they spoke. Indeed, he groups them with other peoples in a short general summary. In this area the languages spoken are Nahuatl and Mixe-Zoquean. Most typical of Olmec art are beautifully worked stone heads in full relief, on which the flattened snout of the jaguar is strikingly treated, yet we have noted that a somewhat similar treatment, but in low relief, occurs in Maya art. Typical, too, are the so-called baby faces, also duplicated in Maya art, and a rather heavy negroid type, parallels to which also exist in Maya sculpture. No writer has discussed Olmec art in detail, but Vaillant (1932) briefly defines the style. Although small portable examples of Olmec art are widely distributed, the only well-known examples on monuments too large to have been moved are located at San Martín Pajapan, Veracruz (Blom and LaFarge 1926, Fig. 43), La Venta, Tabasco (Joyce and Knox 1931; Blom and LaFarge 1926:81-90; Stirling 1939, 1940), Cerro de las Mesas (Spinden 1927; Stirling 1940a), and Tres Zapotes or Hueyapam, where the first colossal head was excavated as early as 1890 (Paso y Troncoso 1892:2:375; Seler Sachs 1922; Weyerstall 1932; Stirling 1939, 1940).

Recent discoveries at La Venta have greatly widened the art range in this field and have yielded information on motifs. The sides of Altar 2 (Stirling 1940:311, 312) carry adult figures holding children

1.11. Bearded type: *a.* stone sculpture, La Venta, Tabasco (after Stirling 1940a); *b.* pottery head, La Venta, Tabasco (after Stirling 1940a); *c–e.* sky-bearers on stone columns, Mexican period, Chichen Itza.

with adult features. One of the adults illustrated has typical Olmec features, yet wears the Aztec Xiuhuitzolli, royal crown, which is also typical of Mexican warriors or leaders of the Mexican period at Chichen Itza. The subject matter—children with adult features held by individuals, usually male—occurs in Codices Fejervary-Mayer, Borgia, and Vaticanus B, and in stucco reliefs on the Temple of the Inscriptions at Palenque, although in the last case the children's faces are missing. Women with children with adult features are represented in pottery figurines from a late Maya Old Empire horizon (Joyce 1933, Pl. III, 12; Thompson 1939, Fig. 92n) and seemingly in Aztec figurines (Fig. 12). A Pipil sculpture at Palo Verde in the style already assigned to approximately A.D. 1200–A.D. 1450 shows a man holding up a child with adult features.

This particular Olmec sculpture, then, can hardly be of great antiquity and, having regard to the combination of the Xiuhuitzolli and the child motif, can best be placed somewhere between A.D. 1100 and A.D. 1520.

Seemingly typical of Olmec art are aged individuals with pointed beards, aquiline noses, and an arrangement of the hair or headdress reminiscent of the liberty cap (Stirling 1940:317, 327; the latter, however, lacks the liberty cap). This identical type is found on sculpture of the Mexican period at Chichen Itza (Fig. 1.11), where he acts as a bacab or supporter of the heavens, but is unknown in Maya Old Empire art.

The placing of individuals in niches on the sides of altars at La Venta is almost exactly paralleled by Monument 8, Tonina (Blom and LaFarge 1926, Figs. 223–29), carrying the date 9.12.10.0.0, and less closely by individuals in niches on stelae at Piedras Negras and Quirigua.

Again one colossal Olmec head shows an oblong ornament pendent from the nose and covering the mouth (Stirling 1940:320). The outlines of this same feature are rather clearly portrayed in low relief around the mouth of the mask on Stela C,

Tres Zapotes. This same oblong decoration is found on pottery figurines which have no appearance of antiquity and which, perhaps, are datable in terms of the Mexican period at Chichen Itza because of the birds in the headdresses (Strebel 1885–1889, Pt. 1, Pl. 2). A somewhat similar plate can be seen on a mask from the Aztec deposits beneath Escalerillas Street, Mexico City (Seler 1902–1923, 2:854).

Spinden (1927), as already noted, is of the opinion that the various stelae he uncovered at Cerro de las Mesas can be dated as approximately thirteenth century.

There is therefore a body of evidence tending to place certain Olmec sculptures at about the time (A.D. 1100–1450) that Mexican influences were strongest at Chichen Itza, and this agrees with the tradition of Olmec pressure against the Pipil and the Nicaragua.

However, it is desired not to deny the claims of Olmec art to a considerable antiquity (Vaillant 1941a, 1941b) but merely to emphasize that this style was of long duration, and that diffusion of certain of its features need not necessarily have taken place at an early date. There is evidence that Olmec art influenced that of the Maya throughout Cycle 9 of Maya history, whereas its later manifestations on the A.D. 1100–1450 horizon had a strong infusion of Toltec motifs and style.

Most typical of Olmec art are the treatment of the muzzle and mouth in anthropomorphized representations of the jaguar and the blending of these feline features with those of a youthful deity. The characteristics of these feline heads are: (1) the flaring nostrils at the base of a narrow nose, (2) most important, the muzzle shaped like a croquet hoop, (3) the triangular or square appendage from the upper lip, (4) the up twist of the lower lip to follow the line of the upper lip and muzzle, and (5) the nick in the forehead.

It has been claimed that Olmec art must be early because of the resemblances of its jaguar masks and heads to the masks on Pyramid E-VII sub, Uaxactun,

but in actual fact of the five characteristics listed above, the latter possess only the appendage from the upper lip. There are closer resemblances to Olmec style in Maya art of Cycle 9 as can be seen in Figure 1.18. The second and third drawings are of jaguar masks on monuments dating from the great period. Both show all listed features except the up twist of the lower lip due to the fact that the lower jaw is suppressed in both cases. The nick on the forehead is replaced, as on some Teotihuacan figurines, by a circle, which, however, is hollowed out, as profile views reveal (Thompson 1932, Fig. 232g). Furthermore, in one case there are dots below the eyes, a common Maya feature in the representation of animals, but one which is absent from the Uaxactun masks, although found on the mask of Stela C, Tres Zapotes.

The appendage from the upper lip is usually represented in Maya art by the T-shaped filing of the central upper incisors. This is one characteristic of the sun god, who not infrequently is depicted with jaguar details, particularly when functioning as god of the number 7. With these jaguar features (particularly the characteristic jaguar 'ear' is often found a band which passes beneath the eyes and is twisted in a loop over the bridge of the nose. The various stages (probably not chronological) in the conversion of this appendage into T-filed central incisors is seen in Figure 1.18f-i. The shield on the panel of the Temple of the Sun, Palenque, shows a jaguar head (note the ears) with the twisted ornament and the triangular appendage. The muzzle is not shaped as a croquet hoop, but another jaguar head immediately beneath has an exaggerated croquet-hoop muzzle. The incense burner from El Salvador has a vestigial muzzle of croquet-hoop form, the twisted ornament, and a beard but no labial appendage. A pottery fragment from Panzamala, Alta Verapaz, has a muzzle of true croquet-hoop shape, supraorbital ridges

reminiscent of those on Olmec jaguars, twisted ornament, and the appendage from the upper lip closely paralleling the T-filed upper central incisors. Finally, a pottery head from Nebaj, El Quiche, now in the British Museum, has a poorly developed croquet-hoop muzzle below a thin nose with flaring nostrils, twisted ornament with dots below the eyes, and T-filed central upper incisors. This type of jaguar sun god occurs throughout the period of the Maya Old Empire.

If these resemblances are significant, Olmec and Maya art styles were influencing one another throughout Cycle 9 very much more strongly than at the time Pyramid E-VII sub was erected, and the masks on that Uaxactun structure cannot for that reason be used to date Olmec art. All that we can say at the present juncture is that Olmec art style appears to have endured for some centuries, during which time, presumably because of its proximity, it influenced the art of the Maya Old Empire, and then, after modification by intrusive Toltec elements, was carried by migrant groups to the northern and southern peripheries of the Maya area.

PROBLEMS OF DATING TRAITS

Having established the probability on the bases of epigraphy, style, and tradition that the Pipil sculptures can best be placed at about A.D. 1100-1450, and having shown that there are some grounds for considering the sculptures from southern Veracruz with hieroglyphic texts as of approximately the same date, and having produced some evidence that Olmec culture may have been flourishing at the same time, we may now look for archaeological evidence of diffusion of objects and style.

Olmec culture does not appear to have been pure. Such features as stone yokes, flat stone heads, pottery heads of the smiling-face type, and typical

1.12. Adult and child: *a.* stone sculpture, La Venta, Tabasco (after Stirling 1940a); *b.* pottery figurine whistle, Lubaantun, British Honduras (after Joyce 1929); *c.* pottery figurine, San Jose, British Honduras (after Thompson 1939); *d.* Codex Borgia, p. 16.

Cerro Montoso polychromes pottery are found not only in the Rio Papaloapam-Tuxtla region but also in the Totonac region to the north. At present there is no definite information whether these features are contemporaneous with typical Olmec sculpture or represent a later diffusion.

The problem is further complicated by the fact that a strong influence from the east coast of Mexico made itself felt in central Mexico. A fresco in a style reminiscent of Totonac has been uncovered at Teotihuacan, but the resemblance is much less marked in the colored reproduction than in the drawing Ramon Mena gives in discussing the Totonac influence (Gamio 1922:1, Pl. 30, and Fig. 149). Other east-coast influences are represented by a sculptured yoke (Lehmann 1910:737) from near the Pyramid of the Sun at Teotihuacan, presumably a surface find; a flat stone head (Plancarte y Navarrete 1911:129) of Totonac type but of a black stone, found at Teotihuacan; and Totonac designs on tripod bowls of Teotihuacan II-III form (Seler 1902-1923, 5:519; Linne 1934, Fig. 117). On the other hand, Teotihuacan II or III figurines are found in Veracruz from Papantla to Los Tuxtlas (E. S. Spinden 1933; Valenzuela 1938, Figs. 5, 29; Weyerstall 1932:32). The peculiar cleft in the foreheads of some suggests a connection with Olmec votive axes, as Beyer (1927:307) has noted.

In addition to these east-coast influences in the general region of the Valley of Mexico, Mexican influences on a Teotihuacan II-III horizon were strong in the highlands of Guatemala during the Esperanza phase at Kaminaljuyu, a manifestation of the wider basal flanged-bowl horizon. There is, therefore, a danger that Mexican elements that entered Guatemala on that horizon may for lack of evidence to the contrary be assigned to a later period. The tombs of Kaminaljuyu, however, serve as a check because of their richness and because the evidence of strong Mexican elements they show gives us a fair picture of the intrusions that were strong at that time. The absence of certain elements, such as yokes and flattened stone heads, from these graves is therefore of aid in establishing their chronological position. These particular absences from the Kaminaljuyu tombs also suggest that the occasional examples of the same objects at Teotihuacan are of later date than the local horizons (Late Teotihuacan II and Early III) contemporaneous with the Esperanza phase.

The date of the Mexican period at Chichen Itza is somewhat difficult to fix, first, because the correlation of the Maya calendar with our own is not yet certain, and second; because there are some grounds for believing that there may have been two separate influxes of Mexican influences at Chichen Itza,

one perhaps as early as A.D. 1000. Vaillant, in the table he prepared for *The Maya and Their Neighbors*; places the Mazapan period, in which fine orange and plumbate occur, about A.D. 1100. Although plumbate lasted but a short while, and other traits to be discussed probably did not endure to within a century of the Spanish conquest, the traditional date of the fall of Mayapan is here utilized as the termination of the period, for the establishing of a definite chronological framework is beyond the scope of this paper.

Bearing in mind the complexity of these interrelationships, let us examine briefly the evidence for placing certain traits in the general A.D. 1100-1450 horizon tentatively assigned to Pipil sculpture and epigraphic material from southern Veracruz. Distributions are shown in Appendix 1. Owing to the paucity of excavation in the areas under discussion, the material objects must be largely those collected for their artistic, rather than their chronological, value.

Stone Yokes and Flat Stone Heads

Stone yokes and flat stone heads are encountered in considerable numbers from Veracruz to El Salvador with a wider distribution of occasional specimens. The occurrence of a plain yoke and a sculptured flat stone head in a burial at Patulul, near El Baul (Gann 1932; 1939:208-209) establishes the fact that these two distinctive types of stone sculpture were contemporaneous. The flat stone head, shaped as a long-beaked bird pecking at the eye socket of a skull (also illustrated in Villacorta 1938:133), is strongly reminiscent of sculptures of the same type from southern Veracruz. A palma of typical Totonac style in the Mexican National Museum carries a similar motif, but the bird is pecking at the side of the skull of a skeleton: The human remains of the Patulul interment were enclosed in two large cauldron-shaped pottery vessels. With the burial were a large number of pottery vessels, several decorated with monkeys in applique. Vessels with crude monkeys in relief are typical of this region, and appear to represent a late horizon (see under Monkey Effigy Vessels). Near the urn were several large pottery figures. The one illustrated by Gann (1932, Figs. 7, 9) is definitely of the type usually accepted as Pipil.

The absence of yokes and flat stone heads from burials at Kaminaljuyu of the Esperanza phase and their nonexistence in the Peten in contrast to their association at Patulul with pottery of a supposedly late date suggest, although they do not prove, the lateness of these two types. The relationship in subject matter to a Totonac palma indicates that the Patulul burial falls in the Totonac horizon, which

1.13. Designs on pottery vessels: *a.* on vessel from Los Tuxtlas, Veracruz (after Valenzuela 1938); *b.* on vessel from Las Flores, Honduras, of Upper Uloa polychrome (after Strong, Kidder, and Paul 1938).

Mrs. Spinden (1933:263) has already placed as contemporaneous with the Mexican period at Chichen Itza (A.D. 1190–1450). Many yokes and Palmas from Totonac territory have typically Totonac designs which would place them on that horizon.

At Matacapán, Los Tuxtlas, in the heart of Olmec territory, fragments of flat stone heads were excavated from beneath the floor of Mound 1 (Valenzuela 1938:14 and Pl. 4). In a lower level was a carved sherd of undoubted late type stylistically related to certain carved vases on expanding annular bases from Isla de Sacrificios, which, as will be shown, are also assignable to the A.D. 110–1450 horizon. Painted sherds in the same level and below the fragments of flat stone heads are mainly of two types. One carries what appear to be glyphs (on one sherd with a bar and dot coefficient) crudely executed in a style which in the Maya area would denote lateness (Valenzuela 1938, Pl. 5). The other style depends for its chief decoration on crosshatching of interiors of rectangles and triangles (Valenzuela 1938, Pl. 6). A remarkable parallel to one of these latter sherds occurs on upper polychrome sherds from Las Flores, Honduras (Strong, Kidder, and Paul 1938, Pl. 5a), which are late (Fig. 1.13). Indeed, painted crosshatching is not infrequent on Uloa Bold Geometric (Gordon 1898, Pl. 3).

In southern Veracruz, then, flat stone heads are as late or later than certain wares which themselves give every evidence of being late, and which can not long antecede the Mexican period at Chichen Itza. If is, of course, possible that these two fragments of flat stone heads were gathered up and thrown into a fill of later date, but in view of the evidence from Patutul and the Totonac tie, this is unlikely. It is also worth noting that one flat stone head (Batres 1905) has a jade bead in its mouth, a death symbol. It shares this distinctive feature with Olmec figurines (Weyerstall 1932, Pls. 4, 5), which in turn seem to be related to faces on late Maya incense burners.

In Escuintla flat stone heads can probably be placed on an equally late horizon through associated pottery also believed to be late.

Plumbate and Fine Orange Wares

Plumbate pottery has been satisfactorily placed on the Mazapan-Mexican Chichen Itza (A.D. 1100–1450) horizon (Merwin and Vaillant 1932:80; Vaillant 1935:121; Thompson 1939:234–36), but it is worthy of note that present evidence now tends to place its center of manufacture in or near western Guatemala, yet the considerable number of plumbate vessels with Tlaloc features would argue against a Maya origin, unless one is prepared to accept the unlikely assumption that Maya potters deliberately catered for foreign markets by decorating their products with the features of the importers' chief god. Possibly Zoque-Mixe or Nahua speaking peoples of eastern Chiapas produced this interesting ware. Representations of tapirs suggest a lowland area, or its vicinity.

Fine orange ware (always untempered?), in the forms of cylindrical or pear-shaped vases, on expanding annular bases or tripod supports, and flat-based tripod bowls, has been shown to be contemporaneous with plumbate (Merwin and Vaillant 1932:80; Butler 1940:262), although fine orange vessels carved with life scenes may be somewhat earlier. Fine orange ware frequently is decorated with Totonac scrolls and other Totonac patterns, which serve to link it with yokes and flat stone heads. Fine orange ware has been satisfactorily placed in the Mexican period at Chichen Itza.

Nicoya Effigy Vessels in Polychrome

Into this same horizon, through resemblances in form, subject matter, and treatment to plumbate, can be brought effigy vessels from Nicaragua, with the head of the animal or person, modeled in the round, projecting from one side of the vessel in contrast to the limbs and minor details which are ren-

1.14. Vessels with central perforation: *a.* of alabaster, said to have come from Mitla, Oaxaca (Peabody Museum, Harvard University); *b.* pottery vessel, Chipal, Alta Verapaz, of Period III (after Butler 1940); *c.* fine orange ware, Utatlan, El Quiche (after Lothrop 1936); *d.* Cerro Montoso ware, Isla de Sacrificios, Veracruz (after Joyce 1914).

dered in low relief. Lothrop (1926:116) has drawn attention to the direct relation to plumbate of this group. The relationship also extends to fine orange ware since at Chichen Itza tall vases of that ware sometimes carry a figure on one side with head in the round, body in low relief, and accessories sometimes incised.

Tecali and Marble Vases

Relief decoration of a kind very similar to that of plumbate, fine orange, and effigy vessels of Nicoya polychrome occurs on vases of tecali (onyx or alabaster) from southern Mexico, particularly from Isla de Sacrificios, opposite Veracruz city, and from Oaxaca. To heighten the similarity, these vases generally stand on an expanding annular base or a tripod support. The unearthing of two tecali vases together with plumbate vessels near Teotihuacan Batres, 1906, Pl. 10) confirms that the two types were coeval. Furthermore, this placement of decorated tecali vessels is substantiated by the discovery of one in the cavern of the High Priest's Grave, Chichen Itza (in indirect association with a vase of fine orange ware on an expanding annular base) under conditions which left no doubt that it was assignable to the Mexican period at that city (E. H. Thompson 1938:61–62, Fig. 24).

Again tecali is linked to fine orange ware by another and much rarer form. In the Peabody Museum, Harvard University, is a tecali vessel with an artificial hole through the center, which is said

to have been found in Mitla. An incomplete vessel of the same unusual form, but in fine orange ware, in the same institution is from Utatlan. A third, in the British Museum, from Isla de Sacrificios is of Cerro Montoso ware, while a fourth, in University Museum, Philadelphia, of red ware, is from Chipal and falls in Period III, the plumbate horizon, which here, too, includes fine orange ware and tecali vessels. The four are brought together in Figure 1.14. Alta Verapaz thus serves to link these three traits.

Tecali vessels without relief are associated with copper at Los Tuxtlas (Valenzuela 1938, Fig. 41), and in Tomb 7, Monte Alban of the Mixtec (Monte Alban V) horizon (Caso 1932, Fig. 34), while the tecali vase with simple decorations from the High Priest's Grave, Chichen Itza, was indirectly associated with copper bells.

In the Uloa Valley and adjacent parts of Honduras are found marble vases, strongly reminiscent of those of the Isla de Sacrificios types, since they are usually cylindrical, and, like those of Isla de Sacrificios, are supported by either an expanding annular base or three feet. On the other hand, the pear shape, so typical of the Sacrificios examples, does not occur in the Uloa area. Whereas, the Sacrificios effigy vases of tecali have a head or body in relief on opposite sides, which might function as handles. The globular form with constricted neck, standing on three solid legs, small and of a truncated cone shape, is found in both areas, and at Los Tuxtlas one held copper bells (Valenzuela 1938). Also com-

mon to both areas are the perforations of walls with simple designs, a feature extremely rare in pottery.

Of particular interest is the strong Totonac feel of the low relief decoration on these vessels in the treatment of volutes and spirals in complex groupings, and the portrayal of faces largely by means of volutes (Fig. 1.15). This whole trend is so alien to art styles of western Honduras, that, taken in conjunction with resemblances in material and form, it surely points to a south Mexican inspiration for the marble vessels.

Pieces of Uloa marble vases are reported as surface finds at Uaxactun (Smith 1936, Pl. 12, Fig. 4) and San Jose (Thompson 1939:167), and thereby these beautiful pieces are placeable in a post-Old Empire horizon or at the very close of the Old Empire.

In the Bay Islands, W. Duncan Strong (1935:93, 143) found pottery imitations of Uloa marble vessels in a deposit which included Polychrome I sherds, a fragment of plumbate, and a small piece of copper. The deposit had every appearance of being of one period, no Polychrome II pottery being encountered. Actually a form common in Polychrome I is very close to that commonest in Uloa marble.

The evidence is strong that tecali effigy vases and Uloa marble vases are closely related. Both must have flourished on a post-Old Empire horizon, that of the Mexican period at Chichen Itza, because of associations with plumbate and copper.

Monkey Effigy Vessels

Evidence has been introduced to show that plumbate, fine orange, Nicoya polychrome, and tecali vases from southern Mexico fall in the A.D. 1100-1450 horizon. In all four cases decoration frequently takes the form of the heads of animals or persons in full relief projecting from the walls of the vessel, arms, legs, and tail being shown in lower relief or forming the legs of the vessel. Sometimes minor details are incised.

In Old Empire art such treatment is extremely rare. The writer knows of but one example, a very unusual vessel from Noh Mul which, because of the associated finds must be placed on the basal-flanged-bowl horizon (Gann and Gann 1939, Pl. 8). In this case there is a pair of heads in contrast to the single head of the plumbate-tecali style.

This style of decoration is also unrepresented in pre-Mazapan deposits in the Valley of Mexico and at Teotihuacan, and has not been reported from the tombs of Kaminaljuyu, but it occurs on the late phase of Alta Verapaz II (Butler 1940, Pl. 6g) and on Mixtec polychrome vessels of late form. Except on incensarios and the lids of vessels, effigy figures are uncommon in Maya art of the Old Empire.

1.15. Volute and scrollwork: *a.* from marble vase, Uloa Valley, Honduras (after Stone 1937); *b, c.* elements in sculpture at Tajin, Veracruz (after E. S. Spinden 1933); *c.* head of snake, slightly weathered, at base of Stela 6, Izapa, Chiapas.

The spider monkey in profile with prominent tail curled at the end is not a decorative motif of Maya pottery of the basal-flanged-bowl horizon. The only example known to the writer occurs on a somewhat atypical squat tripod vessel of black ware in the same chamber that contained the unusual effigy vessel mentioned in the preceding paragraph (Gann and Gann 1939, Pl. 7, no. 3).

Monkeys painted in profile with prominent tail are not uncommon on polychrome pottery of the Piedras Negras equivalent of Holmul V. A very typical example in punctate black ware comes from a tomb of the same period at Mountain Cow (Thompson 1931, Pl. 48), whereas others are shown on vessels of the Tepeu phase at Uaxactun (A. L. Smith 1932, Pl. 3; Thompson 1939, Fig. 2a) and on sherds of the same general horizon from Pusilha (Joyce 1929, Pl. 45).

In western Honduras monkeys are frequently depicted on Yojoa polychrome of Bold Animalistic types. Frequently the head is in relief on the side of the vessel; the body with prominent tail painted on the surface (Yde 1938, Figs. 46, 49, 51, 53). The same general type occurs also in the Uloa Valley (Gordon 1898, Pls. 1, 3), in El Salvador (Spinden 1915, Fig. 68), and on Nicoya polychrome (Lothrop 1926, Pl. 69). But in these areas, the view is not always in profile. Profiles with prominent tail decorate flat pottery stamps of this same period in the Uloa Valley (Gordon 1898, Pl. 11) and flat stamps of the Aztec period. A cylindrical stamp from near Lubaantun, British

1.16. Effigy monkey vessels: *a.* vessel of dark brown ware, south Guatemala (Pullin Collection); *b.* unslipped ware, El Baul, Guatemala.

Honduras, now in Field Museum of Natural History, also carries a spider monkey in profile with prominent tail. This must be a late piece, since engraved cylindrical seals are post-Old Empire. Gann (1918, Figs. 51, 52) illustrates a vessel with annular base of post-Old Empire form on which are depicted two monkeys in profile with prominent tails. Blom and LaFarge (1926:226–233) found in the upper of two burial vaults at Yoxiha, Chiapas, vessels with incised monkeys in profile. There can be little doubt that this burial is assignable to the local equivalent of San Jose IV. E. H. Thompson, in an undated publication, illustrates a vase from Yucatan which is highly reminiscent of Nicoya effigy polychrome. The monkey's head, in full relief, is twisted to one side. Arms rest on knees, both being in relief, while the tail is depicted in low relief on the opposite side of the vessel. The general appearance of this vessel can leave little doubt that it belongs to the Plumbate-Nicoya Effigy-Fine Orange-Tecali horizon.

Monkeys are not uncommonly depicted in relief on the sides of tecali vases, but the tail is swung over the head and grasped by the monkey's upraised paws. One such effigy vessel of tecali is datable since it was found with plumbate vessels near Teotihuacan (Batres 1906, Pl. 10; see also Joyce, 1916).

Although it would be rash to draw the conclusion that the monkey motif is confined to a time subsequent to the basal-flanged bowl horizon, yet there can be no doubt that the spider monkey was an immensely popular subject in the Holmul V and plumbate-Nicoya-effigy polychrome horizons. The latter, however, was that in which relief figures on the sides of vessels were also most common. When, therefore, we find in the Escuintla region vessels

with monkey figures in relief we have good reason to assume, in the absence of contrary evidence, that they are assignable to the Pipil occupation (approximately A.D. 1100–1500), and probably to the first part of this.

As already noted, the grave opened by Gann at Patulul contained monkey effigy vessels as well as a yoke and flat stone head. The monkey effigy vessels, therefore, contribute slightly to the assignment of these associated artifacts to the Pipil occupation.

Chacmool Sculptures

The well-known statues of figures reclining uncomfortably on their backs with trunks slightly raised occur in considerable numbers at Chichen Itza. They can be assigned to the Mexican period because there is hardly a building in that distinctive style without its chacmool (as these statues are called), and because the features and certain insignia definitely link them with that phase. The chacmool concept must have been in vogue in El Salvador at the same time since one at Chalchuapa, El Salvador (Weber 1922, Fig. 39), displays a pectoral identical with those on some chacmoos at Chichen Itza, and which is worn on countless sculptures of the Mexico period but never found on figures of the pre-Mexican horizon.

Colossal Stone Heads

Colossal stone heads have been reported from southern Veracruz, the Pacific slope of the Guatemalan highlands, and from El Salvador. Those from southern Veracruz fall into the Olmec art style, which, as has been noted, certainly survived until shortly before the arrival of Cortes, and which appears to

have reached its apex at the period of Mexican influence at Chichen Itza.

It is highly probable that a class of ovoid stone heads of very much smaller size are related to these colossal heads. One, from Tenaspi Island near San Andres Tuxtla (Blom and LaFarge 1926, Fig. 21), has features which place it in the negroid group of Olmec sculpture. A second, now in Field Museum of Natural History (Holmes 1895–1897, Pl. 55) is reputed to have been found under Lake Texcoco, but, like another piece in the same collection and said to have come from the same region (Holmes 1895–1897, Pl. 50), its style is definitely not that of the Valley of Mexico, and it must represent an import if its provenience has been correctly given. Others may be represented in the Strebel collections (e.g. Strebel, 1885–1889, pt. 2, Pl. 5, no. 13). This ovoid in Field Museum is of a dark, highly polished diorite, and the face represented is that of Tlaloc, although there are no rings around the eyes. As in the case of the colossal head of Tres Zapotes, there is an encircling band at the level of the temples: Since Tlaloc figures are unreported prior to Teotihuacan; this diorite piece presumably can not possess great antiquity, a conclusion perhaps reinforced by the advanced techniques employed in its fashioning. If one can justifiably connect the colossal stone heads with these smaller heads, it follows that great antiquity can not be positively claimed for them either.

Of the colossal heads of Escuintla, that of El Baul is best known. This, however, has a Xiuhcoatl

headdress (Fig. 1.9b) somewhat resembling one from this area of recognizably late date (Fig. 1.9a). Furthermore this head bears such a strong resemblance to a type of portrait found on plumbate vessels that one is led to believe that both were executed in the same art period (Fig. 1.17). The occurrence of colossal heads in the department of Ahuachapan, a center of Mexican influence and in the heart of Pipil territory, is additional, although rather weak evidence, for placing this unusual type of sculpture on the Pipil horizon.

In brief, inconclusive evidence tends to place the colossal stone heads of the Olmec region about A.D. 1100–1450. Slightly stronger evidence supports the assignment of those of the Pacific slope of Guatemala and El Salvador to the Pipil horizon. This unusual concept obviously did not originate independently in the three areas and therefore must have prevailed in all three at the same time, presumably that of Pipil domination, since they occur at Pipil sites.

Deities Falling from the Sky

As already noted, the concept of deities falling from a sun disk, from the sky, or from a celestial monster is absent from Old Empire sculpture with the possible exception of scenes on two or three stelae at Menche (Yaxchilan). It appears suddenly at Chichen Itza in the Mexican period, becoming an extremely common motif. Diving gods are also depicted on late buildings at Tulum, Coba, and elsewhere in this area. Apparently it is unknown in Teotihuacan II–III

a

Olmec types in the Maya Old Empire: *a.* typical Olmec jaguar head on axe in the U.S. National Museum; *b.* mask over head of principal personage, Stela F, Quirigua, dated 8.16.10.0.0 (after Maudslay 1899–1902); *c.* mask over crossed legs of human on Zoomorph P, Quirigua, dated 9.18.5.0.0 (after Maudslay 1899–1902); *d.* conventionalized jaguar face on planetary band forming frame of stucco figure, Temple of Inscriptions, Palenque, dated 9.13.0.0.0 or later (after Maudslay 1899–1902); *e.* head on belt of principal personage, Stela 14, Naranjo, dated 9.18.0.0.0 (after Maler 1903); *f.* mask on shield, Temple of the Sun, Palenque (after Maudslay 1899–1902); *g.* head on incense burner, El Salvador (after Lehmann 1921); *h.* pottery head, Panzamal, Alta Verapaz (after Seler 1901); *i.* head on incense burner, Nebaj, El Quiché (after Joyce 1914).

but is found in Aztec sculpture and in codices of both Aztec and south Mexican origin in use at the time of the Spanish conquest. It is common on Zapotec stelae of uncertain date, and on the later frescoes at Mitla of the Monte Alban Y (Mixtec) period, and is found in a modified form at Tajin (E. S. Spinden 1933, Fig. 6). It is therefore clear that this concept spread into the Maya area at the time of Mexican influence and, if not evolved at about that time, certainly reached it greatest florescence in the four centuries prior to the Spanish conquest. A diving figure on a flat stone head (Munich 1911, Fig. 24) of Totonac style perhaps serves to link these traits.

The Volador Ceremony and Birdmen

There are grounds for believing that the volador ceremony originated in eastern Mexico, and may not have reached the Aztec until after the conquest, for had this striking spectacle been witnessed in the first half of the sixteenth century in the Valley of Mexico, early chroniclers such as Motolinia and Sahagun hardly could have failed to mention it (Krickeberg 1933:71–75). It was, however, performed in the Pipil settlements of Guatemala, as well as in the Guatemala highlands, and among the Mexican-speaking Nicaraos, first cousins of the former. The volador ceremony is depicted in the

Porfirio Diaz and Fernandez Leal codices, believed to be of Cuicatec origin and certainly of late date, as they contain glyphs of Aztec type. It has not been reported from Yucatan.

To the south of Veracruz, particularly in the Papaloapam-Tuxtla region, pottery figurines fashioned as birds or as men dressed as birds are extremely common. Ellen Spinden (1932:269) has called attention to the similarity of stone birdmen from the High Priest's Grave at Chichen Itza to pottery figurines of this type from southern Veracruz. If this similarity connotes contemporaneity, as Mrs. Spinden suggests, seemingly with complete justification, the pottery figurines must, like the stone figures, fall in the period of Mexican influence at Chichen Itza. In any case the best examples can hardly be very much earlier because they are mold-made. The resemblance of some of the more bird-like figurines from southern Veracruz to certain palms (cf. Batres 1908, Pls. 11 and 56 with Strebel 1885–1889[1], Pl. 15, nos. 2 and 6) serves to confirm this dating, since the latter are in Tajin style; which in turn falls about A.D. 1100–1450; as Mrs. Spinden has shown. It is perhaps possible that the Tuxtla statuette and, birdmen statues from Nicaragua also represent participants in the volador ceremony, for it is reported that in Nicaragua some of the performers in this ceremony wore bird masks

(Oviedo y Valdes 1851–1855, Bk. 42, Ch. 11), and the flyers depicted in Codex Fernandez, Leal wear bird headdresses. Furthermore, Torquemada (1723, Bk. 10; Ch. 38) states that the flyers were dressed as birds and descended with outspread wings. Some of the pottery figurines show men with outstretched arms and surely represent participants in the volador ceremony (Fig. 1.10e; Butler 1935:648, Fig. 2h). Several of these figures have a hole in one hand. Could they have been to hold a rope?

Phallic Cults

In reading Garcia de Palacio's account of the Pipil, one is struck by the statement (1860:76) that there was a ceremony of cohabitation at the time the crops were sown. This is quite contrary to the general custom of the inhabitants of the Mexican plateau and of the Maya; among whom continence was generally the prelude to important ceremonies and, among the latter, is still especially emphasized in connection with the preparation of the land for sowing (Ximenez 1929–1931, Bk. 1, Ch. 31; Sapper 1897:281; Thompson 1930:49; Wisdom 1940:441).

Maya Old Empire art and that of central Mexico is remarkably free of eroticism. Indeed, the genital organs are displayed only when animals are represented. In Veracruz and adjacent areas, however, such is not the case. A number of figurines from that region are definitely erotic (Lombardo Toledano 1931, Figs. 52–54; others in the Mexican National Museum; Batres 1908, Pl. 48), and many stone phalli and one of gold were found at Yahualica, Hidalgo, which according to Nicolas Leon, is former Totonacan territory (Genin 1900:32, 38; Leon 1903). The representation in gold and the occasional exhibition of genitals on "Totonac" onyx vases show that this cult was flourishing after the eleventh century.

Phallic emblems are found in a temple at Chichen Itza, which architecturally is of the pre-Mexican period, but these might have been added at a later date, for an occupation of this building during the Mexican period is proved by potsherds and by the fact that it later served as the nucleus of a group of buildings of that period (Vaillant 1933). A nearby temple at Chichen Itza, that of the Little Heads, is, however, definitely of the Mexican period. The two Atlantean figures which helped support the roof have their loincloths drawn to one side deliberately to expose the genitals (Vaillant 1933:26). There is also evidence in literature to support this introduction of phallicism during the Mexican period at Chichen Itza, for of the Itza, the immigrants responsible for the introduction of Mexican features at Chichen Itza, we read in the Chilam Balam of Chumayel, "They brought shameful things when they lost their inno-

cence in carnal sins; they lost their innocence in the carnal sin of Nacxit Xuchit, in the carnal sins of his companions" (Roys 1933:83). Nacxit is Quetzalcoatl, legendary Itza leader. Although famed for his continence, it is related that he was guilty of certain unnatural practices.

Stone phalli also exist at Uxmal, and a series of related sculptures mainly phallic and principally from Telantunich are discussed in a recent paper (Andrews 1939). These last are assignable, to a late period on the somewhat dubious evidence of the glyphs on one sculpture being late, and because of their relationship to erotic figurines of indubitably late date from Santa Rita, British Honduras (Gann 1918:60–62, Pl. 9, Figs. 15, 17). Attention might be called to the extremely important point that there exists a quite marked resemblance between some of the heads on these sculptures at Telantunich and typical Olmec sculpture (Andrews 1939, Pl. 1e, 2a,b).

The evidence indicates that phallicism was most strongly developed in Veracruz, was perhaps carried to Yucatan by the Itza during the Mexican period (A.D. 1100–1450) when they were dominant, and was a feature of Pipil culture on the Pacific slope.

The Eagle Cult

A common design in codices from Mexico is that of an eagle holding in its claw a conventionalized heart. Sometimes a jaguar or puma replaces the eagle. Eagle was one of the names for the sun (Sahagun 1938, Bk. 6, Ch. 37), the temple of the sun was called the home of the eagle, and eagle gourd was the name given the stone vessels in which the hearts and blood, offered to the sun, of sacrificial victims were deposited. A legend recounts that the eagle, by jumping first into the fire, had become the sun. The warrior orders of Eagles and jaguars the members of which donned the skins of that bird and animal, were intimately linked with the sun both because their object was to procure sacrificial victims for the sun's nourishment and because after death in battle they accompanied the sun from his rising to the zenith.

Eagles, jaguars, and an unidentified animal are constantly depicted on sculptures of the Mexican period at Chichen Itza. In their claws they hold hearts (Morris, Chariot, and Morris 1931, Figs. 24–28; Spinden 1913, Pl. 29), but this motif is quite unknown in Old Empire art. It occurs in sculptures at Tajin, placed by Mrs. Spinden in the same period as the Mexican domination of Chichen Itza, and in codices in use at the time of the Spanish conquest (Fig. 1.8). There is, therefore, little doubt that this concept spread to the fringes of the Maya area about

1.19. Interrelationship of traits: broken lines represent connections tenuously established.

A.D. 1200. It occurs at Santa Lucia Cozumahualpa (Fig. 1.8a).

Figures on Pedestals

The distribution in time and space of statues on high pedestals or columns is of some importance, since it has been suggested that they are of Chorotegan origin and the one or two found west of Nicaragua represent an early Chorotegan influence. Actually, there is a fairly wide distribution across Chiapas and up the east coast of Mexico. Unfortunately none are at present datable, but their occurrence in these areas makes it more probable that they were erected during the period of expan-

sion from southern Mexico into the Pacific lands of Central America. If a bone figure described by Caso (1934) can be related to the group by the short pedestal on which it stands, one could equate this style to that of the bone figure, which is the great period of Maya Old Empire art, but this is a very weak link. The interrelationship of these traits is brought out in Figure 1.19.

SUMMARY AND CONCLUSIONS

Certain hieroglyphic inscriptions in southern Veracruz and the Department of Escuintla, Guatemala, form a group which the writer believes to be neither

Maya, Zapotec, nor Aztec. They are characterized by the use of series of bars and dots, without accompanying glyphs, which lie between hieroglyphs with numerical coefficients. These last are almost certainly day signs. The Initial Series introducing glyph is absent, and positions in the 365-day year are not recorded. The glyph less bars and dots do not appear to represent Initial Series of the Maya type counted from a fixed starting point, such as the Maya 4 Ahau 8 Cumhu, but rather would seem to approach closer to the Maya Secondary Series, since there are reasons to believe that they serve to connect the day sign at the head of the inscription with that at the bottom. The actual calculations may have resembled those of the Cakchiquel Long Count in being made in years of 400 days and their multiples. The accompanying glyphs are Zapotecoid in the case of the southern Veracruz inscriptions; the south Mexican type, here called Laud, in the one inscription of this class reported from Escuintla. Both types of glyphs, however, occur together in the same text elsewhere in Mexico. Since the Olmec inhabited the part of southern Veracruz in question and are credited with related art, this hieroglyphic style can be tentatively designated as Olmec.

There is good, but not irrefutable, evidence that all the texts of this type, including that of the Tuxtla statuette, date from the period A.D. 1100–1450. It is probable that this method of recording was extended to the Department of Escuintla at the time of the Pipil migration, which was placed on the same time level by tradition and stylistic evidence, and which was said to have been initiated because of Olmec pressure.

The chronological position of fifteen traits has been discussed, and it has been shown with varying degrees of probability that these were flourishing from the twelfth to the fifteenth centuries of our era. The conclusion follows that therefore most of them were probably disseminated at about that time eastward and northeastward from southern Mexico. Many reappear at Chichen Itza, where it is known that influences from southern Mexico were particularly strong from about A.D. 1200 to A.D. 1450, when the city was dominated by the Itza, foreigners believed to have come from Mexico under the legendary leadership of Quetzalcoatl.

Others are reported from the Pacific slopes of the highlands of Guatemala, El Salvador, and Nicaragua, which were settled by the Pipil and allied peoples about A.D. 1100–1200.

It is not contended that all these elements spread at the same time, still less that all were carried by these two migrations. Some, particularly those of a religious or social nature, may have been carried by

the emigrants, but others may have spread through commercial contacts along well-marked trading and political routes, particularly in view of the identity of interests between the mother lands and the emigrants. Some traits, such as plumbate pottery, may have spread counter to the main northeast and east currents. Although most of the traits under discussion are well represented in the center of radiation, from southern Veracruz across the highlands of Chiapas, it is not suggested that all originated there or migrated thence. Neither is it contended that none evolved in a period prior to that in which they appear to have diffused to the peripheries of the Maya area. On the contrary, there is some evidence that elements from central and southern Veracruz reached Teotihuacan before they spread in the opposite direction. Others, notably marble vessels, may have appeared on the fringes of the Maya area before the Pipil migrations.

Those traits which are common to the Pacific coastal area and to Chichen Itza are with the exception of phallicism found also in central Mexico. These are: fine orange ware, plumbate ware, tecali or marble vessels, diving gods, chacmools, the eagle cult, and figures on relief on vessels (Group A). Yokes, flat stone heads, colossal heads, figures on columns, and the volador ceremony (Group B) are absent in Yucatan and absent or very rare in central Mexico, but are features of the Pacific coast and southern Veracruz.

One explanation of these anomalies would be that each of these groups of traits represents a separate period of expansion, one, a more widespread flocculation, penetrating to Yucatan and to the Pacific coastal area; the other, only to the latter region.

An alternative, and perhaps more logical, explanation would be that the two waves were approximately coeval, but that since the starting points of the migrations or trade routes which carried these traits were 150–200 km. apart (one perhaps near the mouth of the Coatzacoalcos River; the other in south-central Chiapas), influences which reached the one center of diffusion might not have reached the other. Yokes, flat stone heads, and figures on columns seem to have had a wide distribution across Chiapas, and might have been carried by migrants from that area, whereas those who proceeded to Chichen Itza, possibly following a well established commercial route, departed from an area where traits of Group B were absent or no longer strong, perhaps submerged as a result of the break-up of the Toltec hegemony and the resulting migrations. The tradition preserved by Torquemada suggests that the Pipil exodus from south-central Chiapas was in fact an indirect result of the disintegration of that empire, since it is said to

have been caused by pressure from the Olmec, but they in turn had been driven south by the Tolteca-Chichimeca. Thus such influences from central Mexico as were carried by the Pipil had first filtered through an intervening people.

On the other hand the Mexican period at Chichen Itza witnessed the introduction of certain features, such as serpent columns, Atlantean figures, and friezes of prowling jaguars, which are found elsewhere only in central Mexico. The implication is that these influences come indirectly from central Mexico, and probably were spread to southern Veracruz by the Nonoualca-Chichimeca. Moreover the Chilam Balam of Mani mentions the house Nonoual and Tulapan as the starting point of the migration, and this accords with Toltec tradition. Furthermore, the Quetzalcoatl cult, seemingly strongest among the Nonoualca-Chichimeca, gained considerable hold at Chichen Itza, whereas it was rather weak among the Pipil. The rival cult of Tezcatlipoca spread neither to Yucatan nor to the Pacific coast. It is not suggested that the Nonoualca-Chichimeca actually reached Chichen Itza, but rather that the Itza had been profoundly affected in their original home by that or some other group which had migrated southeastward as a result of the break-up of the Toltec regime, and in turn had carried to Yucatan traits they had adopted as a result of that contact.

The evidence that the two groups of traits were approximately contemporaneous is indirect and inconclusive, perhaps because of the little excavation in Pipil territory. In this connection it is worthy of note that elements of both groups tend to be found at the same sites on the Pacific slope. Thus yokes and flat stone heads appear to be plentiful in the Santa Lucia Cozumahualpa-El Baul area, where are found not only colossal stone heads but also manifestations of the second group such as the eagle cult and diving gods. Suchitoto and Campana San Andres, El Salvador, yield each a flat stone head and a yoke, and plumbate vessels are particularly numerous in that area (Lothrop 1927a:205). Chalchuapa, where no intensive excavation has been attempted, yields a chacmool and a phallic sculpture.

Salama, also an unexcavated area and, furthermore, a Pipil settlement, has produced a yoke, a statue on a pedestal, and a figurine representing the Mexican deity Eecatl. Such associations may be haphazard, but they do suggest that the traits with which we are dealing largely belong together.

Furthermore, a little stylistic evidence has been produced linking the colossal head of El Baul with sculptures which in turn are closely associated with Group A, and the designs on yokes from Totonac ter-

ritory are so close to Papantla art of A.D. 1200-1450 and to designs on fine orange ware, similarly dated, that there can be little doubt this trait was flourishing in Totonacapan at the time traits of Group A were being diffused.

It seems not improbable that there was a time lag in the case of certain elements of Group B. These may have diffused across Chiapas at an earlier period and then, mixed with what were perhaps more recent elements of Group A, been carried together to the coast of Guatemala.

One is wary of the term complex, now in little repute, because it implies a close interrelationship of all its elements, and, by extension, the components of an archaeological complex should be strictly contemporaneous. Here, however, we appear to be dealing with a loose mass of traits, perhaps not all in use at precisely the same time and in most cases only accidentally related. The term flocculation appears preferable with its implication that in some cases traits cohere, in others they form loose groupings, and may even have been detached from their original functional complex and reattached by historical accident to another group.

It is useless to suppose that the whole history of such flocculations will ever be known, although future research should do much to rectify or refine what is here outlined, in part as a suggested basis for future research and in part as a plea to combine archaeological findings with the immense stores of almost untouched ethnological data preserved for us by the writers of the sixteenth and subsequent centuries. If the main thesis stands, we shall have the framework of a general and rather late knitting-together of Middle American horizons, comparable to that earlier one which embraces Teotihuacan II-III, Monte Alban III, the Peten basal-flanged-bowl phase, and the Esperanza phase at Kaminaljuyu.

Although doubts are expressed in previous paragraphs that the whole thesis is proved to the hilt, yet enough evidence, historical, archaeological, and ethnological, has been amassed to show a definite flow of concepts and objects of material culture in the concluding centuries of indigenous culture.

Evidence has also been adduced tending to show that the Olmec system of recording dates, as on the Tuxtla statuette, was in vogue on this same general time level, and that this system made its appearance on the same horizon at El Baul, a region known to have been settled then by Mexican-speaking immigrants, who by tradition moved from their homes because of Olmec pressure. This calendar and style of glyphs presumably failed to establish themselves strongly at Chichen Itza because the Maya calendar was already firmly entrenched, although

Zapotecoid glyphs occur there principally as names of the conquerors.

Data now in hand can best be interpreted by placing this Olmec type of inscription in the period which was marked by the distribution of plumbate, fine orange, effigy vessels, tecali vases, yokes, and flat stone heads, and in all probability most if not all of the remaining traits discussed, and by accepting the thesis that this method of recording dates was carried from central and southern Chiapas to the Pacific coast of Guatemala by Pipil immigrants about A.M. 1100–1200. The thesis here propounded, if proved to be correct, would perhaps fit best a correlation placing the Spanish conquest of Yucatan somewhere around 11.3.0.0.0 rather than 11.16.0.0.0.

Finally, it must be emphasized that should the second part of this essay eventually be found to be hardly worth the paper on which it is printed, that would in no way affect the argument advanced in the first part. Had this paper appeared in any series other than that of "Theoretical Approaches to Problems," only the first section would have been submitted for publication. It is printed in full in view of the special license afforded by this series to place substantial mattresses under limbs before perching on them. It is intended that within a few years, with further research completed, this paper shall be reissued in amended form, or, it will be supplemented by a second paper incorporating further data, or, if necessary, it may be withdrawn with reasons given for the collapse of the ideas embodied in it.

APPENDIX 1

DISTRIBUTION OF TRAITS

The value of the distribution table given below can be questioned, for its authority varies with the intensity of excavation or exploration in the areas discussed, and even more so with the local development of stone sculpture. Thus, the absence of marble or tecali vases from the Chiapas and Escuintla areas may well be due to the lack of exploration in those regions. On the other hand, the absence of flat stone heads and yokes from Peten and Yucatan is significant, since excavations would have brought examples to light had they been present. Similarly, as such features as the eagle cult and deities peering from the sky are usually represented on stone or paper, the poor development of stone sculpture in Honduras and El Salvador may account for their not appearing in those sections of the distribution table.

Similarly the amount of ethnological data varies from region to region, and this should not be forgotten in noting distributions of the volador ceremony and phallic cults. The reader, therefore, should bear in mind that the absence or great rarity of a trait in areas of intensive excavation and exploration is significant, whereas several recordings of a trait in an area of little exploration suggests that it is well distributed there. It should also be remembered that geographical divisions are intentionally kept to a minimum, otherwise areas, such as La Mixteca, should certainly stand alone.

No attempt has been made to list all examples of a widely distributed trait in areas where it is known to be well represented, but where not more than two entries occur under a trait heading, no more are known to the writer.

VALLEY OF MEXICO AND ADJACENT TERRITORY	
<i>(Region of intensive excavations and exploration)</i>	
<i>Yokes</i>	
Teotihuacan	Sculptured fragment (Lehmann 1910:737)
Valley of Mexico	Museum of the American Indian, Heye Foundation has two labeled as from the Valley of Mexico, but this provenience must be accepted with reserve
<i>Flat Stone Heads</i>	
Teotihuacan	Plancarte y Navarrete (1911:129); also reproduced in Lehmann (1921, Pl. 28)
<i>Plumbate Ware</i>	
Teotihuacan	Batres (1906); Vaillant writes that he is almost certain these came from a Mazapan grave Vaillant (1937:319, 321) remarks that plumbate is found on the Mazapan horizon. It appears to be absent at Tenayuca
<i>Fine Orange Ware</i>	
	Under discussion are tall vases on bell-shaped or tripod supports, tripod bowls with flat bottoms, and vessels with incised black or white slip. There are some grounds for believing that fine orange carved with elaborate scenes antedates the above forms. Vaillant (1937:319) states that fine orange ware occurs on the Mazapan horizon, but gives no information as to forms
<i>Tecali or Marble Vessels</i>	
Teotihuacan	Batres (1906, Pl. 10); these almost certainly from same grave as the plumbate vessels
<i>Deities Peering from Sky</i>	
Colhuacan	Nuttall (1928, Fig. 15b)
Mexico City	Nuttall (1928, Fig. 19)
<i>Eagle Cult</i>	
Valley of Mexico	Sahagun and other early writers

VALLEY OF MEXICO AND ADJACENT TERRITORY—*continued*

Volador Ceremony

Practiced in post-Columbian period, but some doubt that it existed here in pre-Columbian times. Not mentioned by Sahagun, Duran, or other early writers, but witnessed in Mexico City by Torquemada

Chacmool Statues

Tacubaya	Seler (1902–1923, 2: 818)
Valley of Mexico	Tozzer (1927, Fig. 4)
Tula, Hidalgo	Information of H.E.D. Pollock

Colossal Stone Heads

None known to writer

Phallic Cults

None known to writer. Possibly associated with worship of the alien Tlazolteotl

CENTRAL OAXACA

(Intensive excavations only in Oaxaca Valley)

Yokes

None known to writer. Señor Jorge Acosta informs me that none has been found in the course of eleven years of excavation at Monte Alban

Flat Stone Heads

Oaxaca	Seler (1902–1923, 5:553–54) illustrates various said to come from Monte Alban, Xoxo, and Mitla, but Señor Jorge Acosta informs me that none has been found in the excavations at Monte Alban; Thord-Gray (1923, Fig. 34)
La Mixteca, Oaxaca	Fragment. Information of Señor Jorge Acosta

Plumbate Ware

La Mixteca, Oaxaca	Caso (1938:54. Seler 1902–1923:5, Pl. 81)
Etla, Oaxaca	Seler (1902–23:5, Fig. 237)
Oaxaca	Noguera (1930, Fig. 36d?)

Fine Orange Ware

Oaxaca Valley	End of Monte Alban IV or beginning of V; Vaillant (1941b)
---------------	---

Tecali or Marble Vessels

Monte Alban, Oaxaca	Monte Alban V; Caso (1932, Fig. 34).
Xoxo, Oaxaca	Saville (1900)
Mitla, Oaxaca	Example in Peabody Museum, Harvard University (Fig. 1.14d)

CENTRAL OAXACA—*continued**Deities Peering from Sky*

Monte Alban, Oaxaca	Common on Zapotec stelae; see Caso (1928)
Mitla, Oaxaca	Mixtec (Monte Alban V) period; Seler (1904a, Pl. 37)
Codices	Nuttall and other codices of this group reveal many scenes of this type
Xoxo, Oaxaca	Diving god; Seler (1902–1923, 2: 325)

Eagle Cult

Codex Porfirio Diaz and other codices, such as Borgia, Selden. Laud perhaps more referable to other parts of southern Mexico

Volador Ceremony

Cuicateca	Represented in Codices Porfirio Diaz and Fernandez Leal
-----------	---

Chacmool Statues

None known to the writer

Colossal Stone Heads

None known to writer

Statues on Pedestal Columns

Jamiltepec, Oaxaca	Peñafiel (1890, Pl. 138)
Santa Cruz Tututepec, Oaxaca	Peñafiel (1890, Pl. 225)

Phallic Cults

Monte Alban	Danzantes of Period I not infrequently have erotic aspect
-------------	---

CENTRAL GUATEMALAN HIGHLANDS

(Average exploration and excavation)

Yokes

Kaminaljuyu	Fragment in Museo Nacional de Guatemala
Solola	Seler (1902–1923, 3:627); if this refers to the department, not the town of that name, the yoke might fall in the Escuintla area, since Pipil settlements occur in the south of the Department of Solola, which belongs to the coastal slopes rather than to the highlands)
Salama	Museum of the American Indian, Heye Foundation, but this is a Pipil settlement

Flat Heads

Totonicapan	Munich (1913:326)
San Cristobal, Totonicapan	Field Museum Natural History, Chicago
Without proveniences	Two in Ethnographic Museum, Rome; one in Museum of the American Indian, Heye Foundation; one in University Museum Philadelphia (Joyce 1912, Fig. 8). These might be from Escuintla, western or southeastern Guatemala

CENTRAL GUATEMALAN HIGHLANDS—*continued**Plumbate Ware*

Widespread throughout central highlands. Center of manufacture possibly western Guatemala, although Tlaloc type suggests a non-Maya origin, perhaps southeast Chiapas

Fine Orange Ware

Utatlan, El Quiche Two. Lothrop (1936, Figs. 78, 79); but note Maya design)

Chipal, Alta Verapaz Tripod bowl with black painted meander in University Museum, Philadelphia (NA 11434)

Tecali or Marble Vessels

Primitive examples in no way related to the forms under discussion were found in tombs of the Esperanza phase at Kaminaljuyu

Deities Peering from Sky

None known to writer. What may be a diving god is represented on an incensario from Amatitlan in Museum of the American Indian, Heye Foundation

TOTONACAPAN AND ADJACENT TERRITORY

(Average exploration and excavation)

Yokes

Central Veracruz Widely distributed; see Ernst (1892); Fewkes (1907); Genie (1928); Seler (1902–1923, 5:410); E. Spinden (1933); Strebel (1890); etc.

Puebla Lombardo Toledano (1931, Figs. 12, 13); E. Spinden (1933, Pl. 14)

Tuxtepec, Oaxaca Plain fragment in Oaxaca Museum

Cuicatlan, Oaxaca Beyer (1924–1927:274)

TOTONACAPAN AND ADJACENT TERRITORY—*continued**Flat Stone Heads*

	In this region flat stone heads appear to merge into palmas and are somewhat rare in central Veracruz
Veracruz	Fewkes (1907, Pl. 121h)
Coatlantan, Veracruz	Strebel (1885–1889:2, Pl. 14)
Papantla, Veracruz	In Diego de Rivera collection. Photograph in possession of F. R. Pleasants
Hueytamalco, Puebla	Lombardo Toledano (1931, Pl. 9)
Yohualichan, Puebla	Lombardo Toledano (1931, Pl. 8)
Jalapazco, Puebla	Seler (1902–1923:5, Pl. 76)

Plumbate Ware

Central Veracruz	Widely distributed; see Joyce (1914, Pl. 18); Strebel (1885–1889, Pl. 29, nos. 14–17, Pl. 30, no. 13)
------------------	---

Fine Orange Ware

Isla de Sacrificios	Joyce (1914, Pl. 18, no. 10); Vaillant (1927, Fig. 384); Strebel (1885–1889, pt. 2, Pl. 30, no. 18?)
Tlaxcala	Vaillant (1927:120)

Tecali or Marble Vessels

Isla de Sacrificios	Nuttall (1910)
Soncautla, Veracruz	Lehmann (1907)
Jalapa, Veracruz	Lehmann (1907)

Deities Peering from Sky

Tajin, Veracruz	E. S. Spinden (1933, Fig. 6)
Mixteca, Puebla	Saville (1922, Pl. 1)
	A remarkable flat stone head in the Munich Museum carries a diving figure with features perhaps those of a monkey

Eagle Cult

Tajin	E. S. Spinden (1933, Pl. 13a)
Cempoallan, Veracruz	Paso y Troncoso (1892:2:311)

Volador Ceremony

	Totonacapan seems to have been the home of the volador ceremony; see Krickeberg (1933:71–75)
--	--

Chacmool Statues

Cempoallan, Veracruz	Seler (1902–1923, 5:154)
Hacienda Mixco, Tlaxcala	Peñafiel (1890, Pl. 316)

Colossal Stone Heads

	None known to writer
--	----------------------

TOTONACAPAN AND ADJACENT TERRITORY—continued

Statues on Pedestal Columns

Xico Viejo, Veracruz	Fewkes (1907, Pl. 106)
----------------------	------------------------

Phallic Cults

Yahualica, Hidalgo	Genin (1900:32, 38)
Puebla	Lombardo Toledano (1931, Figs. 52–54) illustrates a series of crude phallic figurines from Totonac territory of Puebla and adjacent parts of Veracruz. Others are in the Mexican National Museum
Morelos	Codex Magliabecchi, f. 29

SOUTHERN VERACRUZ AND ADJACENT WEST TABASCO AND NORTH OAXACA

(Little exploration; some excavation)

Yokes

Southern Veracruz	Beyer (1924–1927:272) notes that <i>Yokes</i> appear to be commoner in southern Veracruz than in actual Totonac territory
Santiago Tuxtla, Veracruz	American Museum of Natural History; Paso y Troncoso (1892:1:85); plain
Los Tuxtlas, Veracruz	Batres (1908, Pl. 22)
Paraiso Novillero, Veracruz	Genin (1928)
Tlacotalpan, Veracruz	In school museum; Paso y Troncoso (1892:1:92, nos. 47–52); four sculptured; two plain with closed ends
Tres Zapotes, Veracruz	Stirling (1938)
Juil, Veracruz	Batres (1908, Pl. 5?)
Garrabato, la Hoya de, Veracruz	Beyer (1924–1927)

Flat Stone Heads

Capoapam Island, Coatzacoalcos River, Veracruz	Seler (1902–1923, 5:555)
Matacapam, Veracruz	Valenzuela (1938:14, Figs. 64, 65); Mariscal (1940)
Sotavento coast, Veracruz	Batres (1905, Pl. 13); Paso y Troncoso (1892:1:93, 97, 98, nos. 56 58, 154, 161)
Los Tuxtlas, Veracruz	Paso y Troncoso (1892:1:85, 89)
Tabasco	British Museum; skull; Paso y Troncoso (1892:1:79); skull

Plumbate Ware

Los Tuxtlas, Veracruz	Seler Sachs (1922, Pl. 6, 34). Mr. Karl Ruppert states that among sherds excavated at Los Tuxtlas in 1939 were a few in all probability from plumbate vessels
Mixtan, Oax	Valenzuela (1941)
Playa Vicente, Oax	Valenzuela (1941)

Fine Orange Ware

	None known to writer, but many sherds of untempered (7) fine orange ware of varied forms found in this region

Gann (1918:62); belongs to late period

APPENDIX 2

ARGUMENT AGAINST THESIS

One of the principal objects in publishing this theoretical reconstruction, as already noted, is to achieve solid progress through stimulating criticism of such of its arguments as are untenable. On concluding the case it seemed advisable to put oneself in the position of a hostile critic and note where the whole argument or specific points are most open to attack. A few of these bases for criticism are given below as possible leads to issues worth special investigation.

1. The reconstruction of the supposed Olmec type of inscription is pretty shaky, for only the Tuxtla statuette is complete and fully legible. Another such full inscription would go far to prove or disprove the suggested 400-day period, but this, of course, is a secondary speculation which in itself in no way affects the general argument.
2. Assumption seems unwarranted that all Olmec art is late because all which appears datable on stylistic grounds fits best into that period. The same applies to Totonac art (Vaillant 1941 and 1941a).
3. Strong tendency to assume that the presence of the same motif on two or more monuments implies that they are of approximately the same date. In Maya art motifs continued over long periods. For example, with regard to the deity peering from the sky or sun, may the important point be not that it occurs on both Monument 1, El Baul, and demonstrably late monuments at Santa Lucia Cozumahualpa, but that its presentation on the former is in a different style?
4. Much stress on negative evidence, the absence of certain features, plumbate for instance, might be due not to the time factor but to questions of trade routes and uneven penetrations of foreign influences.
5. If all sculptural art at Santa Lucia Cozumahualpa is attributable to the Pipil, why are so many of its features absent in El Salvador? Would it not be more reasonable to assume that traits such as the huge stone heads represent one wave, the ball-game players and eagle-sun cult another? Or should one suppose that the group detached, according to tradition, at Escuintla was an ethnic subdivision with its own art style? Should one, attribute the fact that no colossal stone heads are known from central Chiapas to lack of sufficient exploration of that country? Why no chacmools in the Escuintla area?
6. Totonac style is dated about A.D. 1100–1450, but Totonac designs on Teotihuacan pottery and a fresco appear to be earlier. A time lag in central Chiapas offered as an explanation looks rather like fitting facts to the theory.
7. Some stelae at Quirigua carry scrolls resembling those supposed to be peculiar to Totonac art. If these are derived from the same influences as those which placed them on fine orange ware and Uloa marble vases, perhaps these latter should be placed on an earlier horizon, that of late Old Empire, together with plumbate and Nicoya effigy wares. Tombs at San Agustin Acasaguastlan have yielded an association of plumbate and polychrome wares reminiscent of those of late Old Empire, which would tend to support this attribution, but material in Alta Verapaz tombs negatives it. If, as is probable, these Quirigua scrolls have no bearing on the subject, they serve to warn of the dangers of picking isolated stylistic traits as links.
8. Although evidence for the spread of the various traits over much of Middle America in the centuries immediately preceding the Spanish conquest has, on the whole, been well demonstrated, the crucial point, the association of these with the supposedly Olmec calendar, is quite weak.
9. Zapotec culture is almost omitted from the picture. Because of its importance and geographical position, one would expect it to have played an important part.
10. Tlaloc vessels were found in the tombs of the Esperanza phase at Kaminaljuyu. Had these not yet been discovered, the type would almost certainly have been attributed to a later horizon in Central America, and their late appearance there reconciled with an early appearance at Teotihuacan by invoking the idea of delayed diffusion. This well illustrates the pitfalls of attempting to illuminate history with nothing better than a farthing dip. Actually, there appear to be certain differences which eventually may permit of a division of these Tlaloc vases into early and late styles.
11. Would not the whole problem be simplified by extending the last ceramic phases of the Old Empire to coincide in part With the Mexican period at Chichen Itza?

APPENDIX 3

NOMENCLATURE OF ESCUINTLA MONUMENTS

Proposed nomenclature of monuments at the sites in Department of Escuintla, Guatemala, discussed in this paper:

The Fish as a Maya Symbol for Counting and Further Discussion of Directional Glyphs

J. Eric S. Thompson

CONTENTS

- Outline of Discussion
- Identification of Glyphic Elements Representing Fish
- Evidence for Identification of Fish Through Substitution
- Suggested Meaning of Fish and Associated Signs Applied to Various Texts
- Possible Evidence for Rebus Writing
- Concordance between Records of Dates on Stelae and in the Book of Chilam Balam
- Additional Examples of Anterior Date Indicator
- Snake or Eel Variant of the Anterior Date Indicator
- General Remarks
- References
- Illustration

OUTLINE OF DISCUSSION

In a previous paper (Thompson 1943) I reported the two glyphs, both head and normal forms, commonly used to indicate the starting and ending points of a count. For convenience these glyphs were temporarily labeled "A" and "B." In general usage they might be termed respectively "posterior date indicator" and "anterior date indicator,"

for, apart from whether the distance number is to be counted forward or backward, the former always indicates the later in time of a pair of dates; the latter the earlier. Nevertheless, it should be remembered that these terms do not translate the Maya expressions, for the idea of counting almost certainly enters both glyphs. Any truly descriptive term used for either of the two glyphs, however, would be too clumsy. Collectively, the glyphs might be termed "directional counting glyphs."

In the paper cited it was pointed out that the normal form of the main element of both indicators was the same as that often used for the day sign *Muluc* 'water,' and that the head variant appeared to be that of a fish. At the time that identification was made, its importance was not realized. Since then further research has shown that this identification may be of the highest importance.

I must use rather involved arguments in attempting to establish that the head form which is the main element of both directional glyphs is that of an anthropomorphized fish, and that the head or full picture of a fish is a general symbol for counting. In order to make the presentation easier to follow, I give below the main steps in the thesis:

1. Identification of the head variant of the central element of the directional counting glyphs as the head of an anthropomorphized fish by comparisons with realistic and conventionalized representations of fish in Maya art and epigraphy.
2. Identification of the flattened-head prefix as that of a fish.

3. Evidence that the comb element can be replaced in several glyphs by a fish or by the head tentatively identified as that of a fish.
4. Evidence for the interchangeability of supposed fish head, the fish-head prefix, the nicked and dot bracket prefixes, and the comb.
5. Assumption that glyphs that can be substituted for one another without perceptibly changing the meaning of the text must have the same or very similar meanings.
6. Evidence that the various glyphic elements already discussed can be translated as 'count' or 'counting,' and that the interpretation 'end' given to several of them is highly doubtful. Discussion of the hand and affix combination as a symbol for completion, and evidence that it is not interchangeable with other glyphic elements discussed.
7. Linguistic evidence that the Yucatec word for counting was also used as the name of a poorly defined group of large fish. The implication is that the use of the head of a fish as a symbol for counting is an example of rebus writing.
8. Discussion of the resemblances in the manner of recording dates on stelae and in the books of Chilam Balam.
9. Additional examples of anterior date indicators, and a list of all known examples in which the eel or snake prefix replaces the anterior date indicator.

IDENTIFICATION OF GLYPHIC ELEMENTS REPRESENTING HEADS OF FISH

Five Maya pictures of fish are shown on Figure 2.1a–e. Others are to be seen in Maudslay (1889–1902:4, Pl. 93), Seler (1902–1923, 4:705–711), and Tozzer and Allen (1910, Pls. 5, 6). As far as the heads of these fish are concerned, a characteristic feature is the finlike prolongation at the back of the top of the head. This presumably represents the start of the dorsal fin. The gill opening is also prominent, but at times seems to blend with a lateral fin or with what may be barbels. I would call particular attention to the barbels (?) sweeping upward before the forehead and curving downward behind the mouth (Fig. 2.1a, d). Serrated teeth are sometimes displayed. Most naturalistic fish in Maya art are fresh-water varieties, since they are usually shown feeding on water lilies. Fairly naturalistic fish are incorporated into the Initial Series Introductory Glyph on Stelae C and D at Copan, and on Lintel 3 at Piedras Negras (Fig. 2.1e) replacing the usual comb element. The frontal sweep of what may be barbell is usually shown, but the curving sweep around the mouth is absent except, perhaps, on the fish on the left of the Initial Series Introductory Glyph on the south side of Stela C, Copan.

On Stelae P and 16, Copan, the "comb" element in the Initial Series Introductory Glyph is not replaced by fairly naturalistic fish but is combined with conventionalized heads which are rather close to glyphs. Although the design is far from clear, I think that in view of the other substitutions, these, too, must represent fish (see also Goodman 1897:83): The curving lines, which may represent barbell off, perhaps, fins moved forward from their natural positions to serve as identification marks, are prominent (Fig. 2.1f). Glyphs representing offerings of fish in the Dresden Codex have the finlike prolongation at the back of the head prominently displayed, and pictures of fish in the same codex have lines at the back of the mouth corresponding to those already discussed.

The same creature, with these prominent curving lines near the mouth and others curving like an elongated S around the rose and with the same ornament at the back of the top of the head, serves as the patron of the month Zotz, being placed in the Initial Series Introductory Glyph (Fig. 2.1g, j). In some cases the nose is prolonged to become an elongated and upturned snout, such as is typically found in Maya representations of reptiles. This is not a constant feature. Perhaps, if our identification of this creature as a fish is correct, it represents the elongated snout of the shark. Serrated teeth are prominent.

There can be no doubt that the head variant form of directional counting glyphs represents this same animal, for the curving sweep of lines around the corner of the mouth or dust above it, and the accompanying curve in front of the nose and the peculiar arrangement at the back of the crown of the head are prominently featured. Furthermore, the elongated and upturned snout is sometimes shown and the teeth are often pronounced (Fig. 2.1k–t). Again this same creature sometimes forms the main element of the month sign Mac, for the sweeping curve around the mouth and the prolongation at the back of the head are to be seen in various examples (Fig. 2.1w, x).

Sometimes this head, highly anthropomorphized, forms a separate glyph, presumably to indicate a count, but as that point cannot be proved, owing to the nature of the texts, this variant will not be considered. Examples may be seen on the Temple of the Cross, D8 and D16, and on the Temple of the Foliated Cross, L4 and N10, both, at Palenque,

A more naturalistic glyph of a fish from Copan, the meaning of which is not clear, is shown in Figure 2.1u.

Among the many, surely too many, glyphs and affixes to which the interpretation lending has been given is a common prefix obviously representing

2.1. Representation of fish and various glyphs: *a-d*. naturalistic representations of fish in sculpture and ceramics; *e*. naturalistic fish as part of Initial Series Introductory Glyph, Stela C, Copan; *f*. conventionalized head of fish as part of Initial Series Introductory Glyph, Stela P, Copan; *g-j*. heads of patron deity of the month Zotz, Stelae 6, 7, I, and M, Copan; *k-t*. directional counting glyphs (*k*. Seibal; *l-p*. Palenque; *q, r*. Chinikiha; *s, t*. Copan); *u*. fish head as glyph, Stela A, Copan; *v*. fish-in-hand glyph, Yaxchilan; *w, x*. head variant forms of the month Mac (*w*. Altar W, Copan; *x*. Altar 5, Tikal); *y-a'*. supposed fish-head prefixes (*y*. Stela P, Copan; *z, a'*. zoomorph B, Quirigua); *b'*. possible example of directional counting glyph, Stela 32, Naranjo; *c'-e'*. Double Imix glyphs with varying prefixes (*c'*. Stela A, Quirigua; *d'*. Lintel 56, Yaxchilan; *e'*. Lintel 2, Yaxchilan); *f'-h'*. texts with varying affixes, Palenque (*f'*. palace; *g'*. east panel); *i'-m'*. Secondary Series Introductory Glyphs with varying prefixes (*i'*. Seibal; *j'*. Stela D, Quirigua; *k'*. Altar I', Copan; *l'*. Stela 4, Copan; *m'*. Stela 5, Copan); *n'*. Secondary Series and distance number, Dates 22 and 23, Hieroglyphic Stairway, Copan (after Maler 1903; Maudslay 1899-1902; Morley 1920)

the rather flattened head of some member of the animal world. Herbert J. Spinden (1924, Fig. 9d) identifies it as the head of the bird of the mundane era. Beyer (1932:123) recognizes it as the head of a fish. I think there can be little doubt as to the correctness of Beyer's identification. Sometimes the head shows the swinging curved lines around the mouth, which is perhaps the most important attribute of the fish head (Fig. 1y, z, m'). Furthermore, the resemblance to the head of the fish flanking the Initial Series Introductory Glyph on the north side of Stela P, Copan, is very striking. Luckily, however, we have a full-figure representation of this affix in the picture of Glyph C of the lunar series on Zoomorph B, Quirigua. This fantastic creature is clearly a fish because of its bifurcated tail (Fig. 1a'). The ornament at the back of the head is present, there is a sweeping curve around the nose, and what are presumably the barbels are shown as a bearded tuft on the extremity of the lower jaw.

EVIDENCE FOR IDENTIFICATION OF FISH THROUGH SUBSTITUTION

In the portraiture of mythological animals the Maya were even less governed by nature than is Walt Disney, and, in addition, merged the characteristics of the creatures they depicted with a bewildering latitude not found even in our animated cartoons. It is possible, unfortunately, to run the gamut from fish to jaguars by a series of minor transitions so that one can not always be certain whether one is dealing with fish, flesh, fowl, or good red herring. It is therefore necessary to check as far as possible the identity of the glyphs assigned to the piscatorial world purely on the evidence of the style of delineation. There are two collateral lines of evidence, substitution and meaning.

As already noted, fish, naturalistic or highly conventionalized, can be substituted for the comb element in the Initial Series Introductory Glyph. Since the translation is thereby unchanged, fish and the comb element should have the same meaning. If it can be shown that the comb element can replace the glyphs tentatively identified as heads of fish, clearly their identification as such is correct.

There are two glyphs of known meaning in which the comb element occurs, excluding for the moment the Initial Series Introductory Glyph and the katun sign. These are the month symbols Mac and Tzec. Mac is the most variable of month signs, there being three common variants. Whatever the form of the main body of the glyph, the superfix is almost always of the same form on the monuments, being that generally found above the so-called

lahuntun glyph. Nevertheless, this superfix can have little importance, since it is absent from Mac glyphs in the codices, the main body of the glyph may be in the form of an Imix with a variable infix or it may be the grotesque face similar to that found with the directional counting glyphs, tentatively identified as that of a fish (Fig. 2.1w, x). When this head variant replaces the Imix element, the comb or combs, invariably found with the Imix form, are dropped. I think the only possible interpretation is that the head variant becomes the main element, substituting for the comb postfix (usually placed as a suffix, but rarely to the right of the glyph, as on Stela 13, Yaxha). That is to say that this head variant has the same meaning as the comb, just as the fish on each side of the Initial Series Introductory Glyph are interchangeable with the comb.

The third Mac variant appears to be confined to Yaxchilan. Both the comb and the tentatively identified fish are absent. The main element rather resembles Beyer's "serpent segment," but the various possibilities are too involved to discuss at this time. Suffice it to say that a good case can be made out for supposing that this element represents a fish. (Imix types of Mac may be seen in Morley (1920:3:135, nos. 3, 4, 7; Morley 1937-1938, Pls. 25c, 34m, 37h, 49b). The assumed fish variant is illustrated in Bowditch (1910, Pl. 10, nos. 1-3, 5, 6; Morley 1920:135, nos. 1, 2; Morley 1937-1938, Pls. 8g, 25b, h). The Yaxchilan variant is shown in Morley (1937-1938, Pls. 21o, p, 22i, 24m, 25p).

Tzec is almost invariably shown in its normal form, the Chuen element and a comb superfix. It occurs as a head form with the Chuen element as an infix but the comb suppressed on Stela F, Quirigua. Details can not be made out, but there is a projection in front of the forehead which may represent the curving sweep of lines typical of the head of the fish and which it has been suggested represents barbels or a lateral fin. A similar feature is visible on the head variant on Stela J, Quirigua. On Lintel 41, Yaxchilan, Tzec is represented as a grotesque head with prominent teeth. The Chuen element forms the head and the whole is surmounted by the comb element. The head does not look very piscatorial, but there is no particular why it should be so, in view of the presence of the comb element. Thus, although the evidence for a substitution of the head of a fish for the comb element in examples of Tzec is far from conclusive, yet it does, as far as it goes, tend to support such a substitution.

Hermann Bayer calls the comb element "eyelash." In his detailed study of the hieroglyphs of Chichen Itza (1937:38, 98; Figs. 131-136) he shows how a head which he identifies as that of a fish is

substituted for the “eyelash” (i.e. comb element). Other examples of this substitution are given in his Figures 1–14. In some cases these highly conventionalized heads of fish resemble the Yaxchilan variety of Mac.

There is one possible case of the comb element replacing the assumed fish head or the Muluc normal form in a directional counting glyph. This occurs on Stela 32, Naranjo. On the front of the celestial throne, at the foot of the monument, are incised fifteen glyph blocks (Morley 1937–1938, Pl. 92d. The last glyph records 8 Ahau, an abbreviated reference to 9.19.10.0.0 8 Ahau 8 Xul, the dedicatory date of the monument. The penultimate glyph is the possible directional counting glyph, a posterior date indicator (Fig. 2.1b'). Landa's “i” prefix is present, and so is the flame affix, but the latter is located as a prefix instead of standing in its usual position as a postfix. The central element is replaced by the comb, and there, in addition, a trinal suffix which is presumably ornamental. There is no distance number connecting the last date with 8 Ahau but in rather cases, particularly on late monuments, a directional counting glyph is carved where the distance number has been suppressed. A more serious objection to accepting this glyph as a posterior date indicator is that it also occurs earlier in this text, unassociated with either a distance number or a Calendar Round date. There are cases where directional counting glyphs occur under similar circumstances, presumably to record some astronomical or ritualistic reference, but the combination of this unusual form and its use under dubious conditions leads one to accept the identification of this particular glyph as a posterior date indicator with hesitation.

Rarely, the whole body of a fish is substituted for the comb in compounds. Beyer, in the paper, just quoted, gives one example (Fig. 542) and Morley (1937–1938, 2:557) notes another in the case of the double Imix glyph which not infrequently closes an inscription (Fig. 1c', e').

The prefix identified as that of a fish (Fig. 2.1y-a') can be substituted at will for the so-called ending bracket (Beyer's “fire teeth”). In this group also belongs a variant form in which a line of dots is enclosed within the bracket. I think this is a variant of the comb prefix since on some of the combs which flank the Initial Series Introductory Glyph there is a line of dots before the teeth of the comb.

Attention has just been called to the substitution of a complete fish for the usual comb of the double Imix. The dot-bracket variant can also be used as a substitute (Fig. 2.1d').

A glyph with crosshatching and a comb postfix occurs in a text at Palenque (Fig. 2.1f'). The same

glyph with a dot bracket and followed by the same glyph occurs elsewhere at Palenque (Fig. 2.1g'), whereas in several other examples these postfixes are replaced by a head which is almost certainly that of our supposed fish, since it is in conformity with Palenque forms of the central element of the directional counting glyph. In the case illustrated (Fig. 2.1h') the context is the same. Another example of the interchangeability of the nicked-bracket affix and comb is supplied by a jade bead from Tzibanche, Quintana Roo, for brackets replace combs on each side of the superfix recording 4 katuns (Gann 1935; Beyer 1932a). Such a substitution is not particularly surprising, for all the elements of the bracket, the curved line, the V nick, and the flanking small circles, are worked into the comb elements of the Initial Series Introductory Glyph on the south side of Stela P, Copan, and, less clearly (the circles have been reduced to semicircles), on Stela 7 at the same site.

The nicked-bracket affix can also replace our supposed fish glyph without altering the meaning. Stela D, Pusilha, supplies an example. The nicked-bracket prefix is substituted for the assumed fish head (or the Muluc variant) as the main element of an anterior date indicator. The reading is clouded, but the glyph lies between a distance number of 1.12.17 and a Calendar Round date 5 ? 3 ? which Morley reads as (9.8.0.0.0) 5 Ahau 3 Chen. Possibly this distance number is an error for 1.12.8, which will connect the last date with 2 Lamat 1 Zip, which is the next recorded date on this monument., viz.

9.8.1.12.8	2 Lamat 1 Zip
1.12.8	subtract
9.9.0.0.0	5 Ahau 3 Chen

The dot bracket similarly replaces the central element of the directional counting glyph in a posterior date indicator on the west side of Stela C, Quirigua, which lies between a distance number of 17.5.0.0 and the date 6 Ahau 18 Kayab.

Lintel 30, Yaxchilan, supplies a case where the bracket affix replaces Landa's *i* prefix on a posterior date indicator. I believe this is an erroneous carving, since Landa's *i* prefix conveys the idea of posteriority in time, and does not have the same meaning as the bracket.

The interchangeability of both kinds of bracket prefixes, comb, fish-head prefix, and fish-head glyph is demonstrated by examples of the Secondary Series Introductory Glyph. Examples of all five affixes are illustrated (Fig. 2.1i'–m'). These variations in no sense affect the meaning of the glyph. Indeed the

prefix can be entirely omitted from this glyph without affecting the meaning (Stone of Chiapa).

Finally, to complete the circle one might call attention to the replacing of the fish-head prefix or the nicked-bracket prefix by the fish-head glyph. Such a substitution occurs at Quirigua. The date 9.16.13.4.17 8 Caban 15 Yaxkin is declared by the Initial Series on the west side of Stela D. This date is the second katun anniversary of 9.14.13.4.17 12 Caban 5 Kayab. The anniversary is duly noted, for the date is followed by the hand-shell-tassel combination, the fish head as a prefatory glyph (a glyph which modifies the sequent sign with which it is to be read), occupying a full quarter block, and then 2 katuns.

Beyer (1932:123, Fig. 77) illustrates another example of the fish-head glyph substituting for the fish-head or bracket prefix with the so-called end of a tun glyph.

From the above material it is clear that the comb can be replaced by a complete fish or the fish-head glyph not only in the Initial Series Introductory Glyph but in other glyphs. That the fish-head prefix, nicked-bracket prefix, and dot-bracket prefix were interchangeable has long been known. It is now clear that the bracket prefix can replace the comb and the fish head without alteration of meaning, and the dot-bracket prefix can be substituted for the comb or the fish-head glyph. All these elements therefore must have the same meaning or meanings so close to one another that they could be interchanged at will. Presumably long usage had dictated that certain forms should be used in certain places, for example, the comb affix in the Initial Series Introductory Glyph; but substitutions were permitted just as in English "reckon" can in many cases be substituted for "count."

The free interchange of the comb affix with the elements identified by their delineations as heads of fish demonstrates that these are in truth representations of fish, in some cases partially anthropomorphized, since the interchangeability of the comb affix and naturalistic or conventionalized fish is well established.

SUGGESTED MEANING OF FISH AND ASSOCIATED SIGNS APPLIED TO VARIOUS TEXTS

In my previous discussion of directional glyphs (Thompson 1943) I showed that the central element of those glyphs, the fish head or the Muluc sign, the normal variant, must have a meaning such as count or counting. Clearly if the thesis here advanced is correct, the comb and bracket affixes should also

mean counting, and the various uses of the fish or its head should have the same meaning.

It has already been shown that either a comb postfix or a fish head as main element are constant elements of the usual forms of the glyph of the month Mae.

It has been noted that the normal form of Mac is usually an Imix sign with an infix, the "balls of down" superfix, and the comb as suffix or affix to the right. For a number of years I have felt fairly certain that this Imix sign modified by an infix represented the 260-day period, the misnamed tzolkin, a term unfortunately still used despite the evidence against its authenticity (Long 1934:64). As the end of the month Mac is 260 days from the start of the year, its conclusion also marks the end of a tonalpoualli counted from the start of the year. It is therefore highly logical that the glyph for Mac should mark this. The meaning of the superfix is unknown, but as it is omitted in representations of Mac in the Dresden Codex, and can be omitted from the lahuntun glyph, it cannot vitally affect the meaning of the whole glyph. The Imix, as we have seen, appears to stand for the 260-day period; our thesis requires that the comb element indicate a count. The glyph in that case would mean "260-day count" or "the 260-day period counted,"

The Yucatec name Mac seems to bear out this derivation, for Mac, according to the Motul dictionary, means "to shut by closing a lid or by placing in a box (*cerrar atapando o encaxando*), to shut up or place in reclusion." The 260-day period may well have been considered as occupying a compartment shut off within the haab. The month Tzec, of which the comb is also a component, is 260 days from the end of the tun or haab (i.e., the 360-day period; see Long 1925), not from its beginning. Its conclusion marks the end of 100 days from the start of the haab, with 260 to follow. The main element is akin to the uinal sign. Thus the whole might mean "the uinals counted," with the implication that the remaining 260 days formed a tonalpoualli. The tonalpoualli, then, might be considered to serve loosely as a subdivision of the haab, forming a compartment either at its start or at its end. That is to say that the Maya recognized that the haab could be divided into 260 days and 100 days, just as the 20-day period is divided into 13 days and 7 days in the Chilam Balam of Chumayel.

Combs or fishes combined with the tun sign (and the patron deity of the month) to form the Initial Series Introductory Glyph presumably means something like "the count of the tuns with so-and-so as the patron god." This is plausible, for a count of tuns almost invariably follows in the form of an

Initial Series. The combs often found with the katun sign would similarly indicate in combination with the Cauac element a count by twenties. Actually, elements denoting the head of the fish appear to be present in the head forms of cycle, katun, and tun, blending with the more dominant bird features.

The nicked and dot brackets, as well as the fish-head prefix, have been generally interpreted as having the meaning of ended or completion. The question of the numerous elements classified as ending signs is too involved to be discussed here at length, but a few words must be said to clarify the situation.

The prefixes just discussed are usually treated as though they were synonymous with the well-known prefatory glyph consisting of a hand with various affixes. The hand and shell (or tassel or moon) combination, which is translated as 'end,' almost certainly denotes completion, for it is used as the zero or completion sign with period glyphs in many Initial Series. It is difficult to suggest any other logical meaning for this sign (Whorf 1933:27-30) when it is attached to tun, uinal or kin glyphs of an Initial Series to indicate that they are completed. (We have information in the books of Chilam Balam that katuns, and presumably all time periods were reckoned by their endings). Similarly the hand over a sun glyph, which is the symbol for west, can best be translated as 'sun completed' or 'sun ended.' Also, I think that the use of the hand and a number with Glyph C of the lunar series must indicate "n moons completed" or perhaps even more probably "to the completion of n moons," that is, when the current moon is completed. Similarly Glyph D of the lunar series would state n days after the completion of a moon. I have given some thought to the possibility that the variable positions of the hand may affect the meaning, but that does not appear to be the case in the glyphs under discussion.

Now if the two bracket prefixes and the fish-head prefix were synonymous with the hand and affix combination, there would be no reason why they should not be interchangeable, but they are not. The hand combination can never be prefatory to the so-called hotun glyph, the lahuntun glyph, the Caban glyph, Glyphs B, C, or F of the lunar series or the Secondary Series Introductory Glyph; although in all these cases the bucket or fish-head prefixes are commonly attached. In the other hand neither bracket prefix nor the fish-head prefix can replace the hand in the lower orders of an Initial Series to denote completion or zero, nor can they replace the hand over the sun glyph as the symbol for west.

Sometimes the bracket or fish-head prefixes are attached to the hand combination or to the coeffi-

cient of the sequent glyph which the hand combination modifies. If both sets of symbols indicate completion or ending, one is redundant. It is surely incorrect to translate these signs collectively as 'end of,' for it is improbable that the Maya, addicted as they were to redundancy, would use together a prefatory glyph and a prefix with precisely the same meanings (although the same affix may be attached as both a prefix and a postfix to the same element, as for example in Gates' Glyph 142).

Evidence that the bracket does not mean 'ending' is supplied by Stela 1, Piedras Negras. There the bracket is prefixed to 5 kins (inverted Ahau variant). This is a normal distance number, connecting two Calendar Round dates, and the sense is not end of five days, but a count of five days. It is at the same time, highly improbable that the bracket, comb, or fishhead prefixes attached to the Secondary Series Introductory Glyph could imply completion, for this glyph declares that a distance number is about to be added or subtracted, not that that operation is completed.

Translation of the various prefixes under discussion as 'count' and the hand combination as 'completion,' is logical and in agreement with the ideas already discussed. A text consisting of one of these prefixes, the hand combination and a record of so many katuns (or cycles) would then mean "the completion of the count of n katuns [or cycles]" when the prefix was attached to the coefficient of the period; and "the count completed of n katuns [or cycles]" when the prefix was attached to the hand combination. Such translations, as we shall see, closely parallel those to be found in the Maya chronicles of the Book of Chilam Balam of Mani. In those numerous cases in which the prefix is attached to the period without any hand combination being present, the passage would merely record "n katuns [or cycles] counted" or "the count of n katuns (or cycles)."

Similarly the bracket or fish-head prefix, winged Cauac and hand combination, which is now read as "end of a tun," would mean "count of the tun completed" or "the completion of the tun count," or perhaps "count to the tun completed." Glyph C of the lunar series would mean "the count of n moons completed" where the prefix was present; "n moons completed" where it was omitted (ignoring for the sake of simplicity the possibility that the completion involves the current moon).

A translation of the various prefixes of the Secondary Series Introductory Glyph as 'count' is eminently satisfactory since a reckoning of so many days, uinals; and tuns follows it, The meaning of the main element of the glyph is unknown, but probably means 'time' (cf. the Aztec glyph for feast).

Parenthetically one might remark that the Maya displayed a loquacity in their inscriptions which augurs ill for those hopes we still cherish of extracting much meat from the inscriptions. In the text given in Figure 2.1n⁷ the Maya used nine glyphs to write "11 Ahau plus 11 tuns 14 uinals 6 kins reaches 6 Cimi Tzec." Translated literally, it reads: "A reckoning of time: 11 tuns 14 uinals and 6 kins counted forward from 11 Ahau is counted forward to 6 Cimi 4 Tzec." Three of the glyphs could have been suppressed without affecting the meaning, and the kin sign could also have been eliminated through the transference of its coefficient to the uinal signs. This is a redundancy of nearly 45 per cent, not far short of that of the average broadcaster, but extravagant when each glyph had to be laboriously carved.

These involved arguments show, at least to my satisfaction, that all these various elements, the naturalistic fish, the anthropomorphized head of a fish, the fish-head prefix, the comb element, and the nicked and dot types of bracket prefix, have a single origin and all signify count or counting. However as the nicked-bracket prefix is less interchangeable than the rest, it might be well to preserve this distinction by translating it as 'reckoning,' reserving the word 'count' for translation of the remaining elements. This discussion however, by no means exhausts the glyphs into which the fish enters. There is inconclusive evidence that the hand grasping a naturalistic fish (Fig. 2.1u) may mean the end of a count, in the sense that there is a reversal count, a distance number forward being followed by a backward count. This interpretation is tentative. The problem is complicated by the occasional use of lunar post-fixes, and is too involved to be discussed here.

It is quite probable that the bracket and comb affixes have other meanings in texts which do not involve matters of numbers, time, or astronomy. For example, in the various codices these affixes sometimes occur with the glyphs of gods, and so almost certainly do not in such cases carry the meaning of counting. Such matters are too involved to be discussed at this time.

POSSIBLE EVIDENCE FOR REBUS WRITING

Considering it possible that fish might be a form of rebus writing for count, I enlisted the aid of Ralph L. Roys. The usual Maya word for counting is *xoc*. The Motul dictionary gives the meanings 'to count,' 'counts,' 'to pray by telling [rosary] beads' and *xoc huun* 'to read.' Literally, this last would mean to count a book, but as Maya books largely consisted of dates and the intervals between them, the term is perfectly appropriate. The Motul dictionary also

gives *u xocan haab*, *u xocan kin* 'all the years or each year,' 'all the days or each day.' Actually the meanings here must be literally 'the count of the years,' 'the count of the days.' The word *xoc* is used in the Chilam Balam of Chumayel in the sense of counting, for on page 63 we read "*u tzolan kin zanzamal licil u xocol*" which Roys translates 'every day is set in order according to the count.' *Tzol* and *tzolan* carry the idea of setting in order, but they seem to have been interchangeable with *xoc*. On pages 22 and 23 of the Chilam Balam of Chumayel we find "the count [*tzol*] of days in one year, 365," and "the count [*xoc*] of days in a week . . . seven." The first chronicle is called "A record of the count [*xocan*] of the katuns," and the auguries used by modern Maya to tell the weather of the coming year is called the *xoc kin* (Thompson 1930:75), although this form of prognostication is of European derivation. In the Chilam Balam of Mani we read "The count [*xocol*] of 11 Ahau was not ended when the Spaniards . . . arrived," and "six years were lacking to the termination of the count [*xocol*] of 13 Ahau."

The word *xoc* (or *xooc*, for the duplication of vowels in Yucatec is seldom significant) has, however, another meaning, that of some large fish. Mr. Roys informs me that in the Vienna dictionary *xooc* is given as 'shark, the teeth of which the Indians remove to shoot arrows with.' He also notes that the Pio Perez dictionary lists *hkan xoc* as a species of shark, and that George Gaumer (1917:32, 35) identifies this as 'pilot or caaing whale' and as 'short-finned blackfish.' Roys also points out that on page 2 of Chilam Balam of Tizimin, in a section dealing with tun prophecies, there is mention of *chat u-ayab xooc* 'the great [or red] demon shark or whale.' He concludes that *xooc* or *xoc* refers to an ill-defined group of large fish or whales.

In the *Diccionario pokomchi-castellano y castellano-pokomchi de San Cristobal Cahcoh*, which dates from the end of the seventeenth century and the truncated remains of which are in the Berendt collection (Breton 1917), the word *xoc* is listed, with shark given as one of its meanings. However, nothing like counting is included among the remaining translations of the word.

Naturally, it is somewhat difficult to trace such a word in many vocabularies. Compilers, overwhelmingly clerical, would have had little interest in asking natives, who for the most part lived inland, their names for such denizens of the deep as sharks, whales, and perhaps mythical fish, unless a sermon on Jonah was contemplated.

It is possible that the Cakchiquel name for the rainbow, *xocok*, is connected with the mythical *xoc* fish. We are told that the Cakchiquel regarded the

rainbow as a snake, but that is hardly a serious objection, for the mythological creations of the Maya were so variable (cf. the celestial monsters which ranged from alligators to fairly realistic snakes) that cosmological snakes and fishes might well be confused with one another. This rainbow creature was sinister, since Cakchiquel mothers warned their children that if they pointed at it, they would have distorted fingers. I have not found *xoc* as a root for a word signifying counting in any Maya language other than Yucatec. In that connection Roys points to the absence of glyphic material in the Guatemala highlands as suggesting that the calendar was in all probability a creation of the lowland Maya. Actually, vocabularies for the Chol, Chontal, Chorti, and Tzotzil are far from complete, and it is quite possible that the absence of any record of a cognate of *xoc* in those languages or dialects is due to the lack of full word-lists. On the other hand, the word does not occur in the lengthy Tzeltal dictionary. Mr. Alfonso Villa R., who is at present engaged in investigations among the Tzeltal, informs me that the word *xoc* with the meaning of counting is unknown among the Tzeltal and that the term is not employed to designate any species of fish.

The glyph in question does not resemble a shark, but that is hardly surprising when one considers how little the inhabitants of the cosmological and mythical worlds of the Maya resemble their counterparts in nature. The *xoc* was probably a large mythological creature with no immutable characteristics, and with a tendency to become anthropomorphized.

Having reached the conclusion that in all probability the various fish symbols should be read as *xoc* 'count,' I now discuss the affixes of the directional glyphs. One, the flame-like postfix which forms part of both the anterior and posterior date indicators appears to be the same as Landa's glyph for the sound *ti*. This word means in Yucatec 'at, in, with, to, or from.' It is possible, therefore, that the head of a fish and this flame-like postfix together indicate 'count to' or 'count from.'

The affix Landa's *i* occurs only with posterior date indicators. It has already been suggested that it should have the meaning of 'forward.' Beyer christened this glyph, but actually one can seriously doubt that it is the same as Landa's glyph for *i*, although the term is retained. Actually the letter *i* has the meaning of a count not forward but into the past. For example Beltran gives *hobix* 'five days hence,' *hobixi* 'five days ago.' Roys informs me that *i* can apparently convey the idea of past time also in Chol, but it evidently has other meanings, as is certainly the case in Yucatec. However, here the sound is a postfix and the glyph is a prefix. I think this can

be only a strange coincidence, and that the glyph in question does not stand for the sound *i*. Yet the sound *eh* (*ih* in highland Maya) added to the number indicates a count into the future (Noyes 1935). Can Landa's *i* represent that sound? This is a possibility, hardly a probability. Noyes in the article cited brings together examples indicating that the sound *er* or *ir* was added to the number to denote a count into the past.

Among Landa's letters is the comb element, which is given the sound *ca*. This, however, is the first two letters of *cay* (or *cai*), the Yucatec word for fish. Tozzer (1921:19) has claimed that the *ay* or *ai* sound in Yucatec is the only diphthong in that language. However, one might question that. In cognate languages an aspirate may occur between *a* and *i* (e.g. Yucatec *ain* 'alligator,' Tzeltal and Chol *ahin* 'alligator'), and the shift from Yucatec *a* to *i*, Mopan and Chol group *u*, is to be seen in the word for fish (Yucatec *tai*, Tzeltal *chai*, Tzotzil *chai*, Chol *chui*). Stoll (1884), from whom these comparisons are taken, accents the first vowel of *cai* and the cognated words. Finally the Motul dictionary gives examples of the indiscriminate use in writing the same word of a single or double *a* before (e.g. *ah uay xibalba* 'sorcerer who speaks with the demon,' *ah uay chac* 'sorcerer who causes rain by the art of the devil,' *ah uaay* 'sorcerer,' *ah uaay ch'amac* 'sorcerer who takes the form of a gray fox'). Were *ay* a true diphthong, its first vowel could hardly be doubled. Accordingly there seems little doubt that *ca* can be the first syllable of the word *cai* 'fish,' and in a way the use of the comb here as the sound *ca* is confirmatory evidence that 'comb' (probably a conventionalized dorsal fin) was a symbol for fish. Long (1935:27) has disposed of the old idea that *ca* was a form of rebus writing for *kal* 'twenty.' Presumably *ca* could represent fish in general and *xoc* in particular.

CONCORDANCE BETWEEN RECORDS OF DATES ON STELAE AND IN THE BOOKS OF CHILAM BALAM

If the Maya chronicles were old chants or recitations reduced to writing (and much garbled in the process), and if those chants or recitations were also recorded in hieroglyphic form, a supposition warranted by the information that the Maya had hieroglyphic histories, there should be some correspondences between glyphs and chronicles. Unfortunately, the methods of recording dates varied between the Initial Series period of the southern area and the system used in the chronicles, and in parts of Yucatan at much earlier times. The former referred to the katuns by their numerical sequence in the cycle; the latter by

the Ahau days in which they ended. However, a few comparisons may be made.

INITIAL SERIES INTRODUCTORY GLYPH				
Elements:	comb or fish	tun sign	patron god	prefix
Maya:	(u) xocan (or xocol)	tunob	God X u uich	?
English:	the count of	the tuns	God X the face	?

CHILAM BALAM OF CHUMAYEL CHRONICLE (ROYS 1933:74):		
U kahlay	u xocan	katunob
The record of	the count of	the katuns

TYPICAL PASSAGE IN THE CHUMAYEL SERIES OF KATUN PROPHECIES			
Lahcabil	Ahau katun . . .	yaxal chuen	u uich
12	Ahau katun . . .	(the god) Yaxal Chuen	its face

It should be noted that the face in the Introductory Glyph is that of the patron of the month, not of the katun.

PERIOD ENDING GROUP OF GLYPHS (STELA 4, COPAN)			
Elements:	4 Ahau	13 Yax	fish-head prefix
Maya:	Can Ahau	oxlahunte Yax	xocan
English:	4 Ahau	13 Yax	counted
Elements:	hand, tassel, shell		15 katuns
Maya:	u dz'oc?		holhunte katunob
English:	the completion of		15 katuns

CHILAM BALAM OF MANI CHRONICLE				
Maya:	dz'ococ	u xocol	oxkahun	Ahau
English:	completed	the count of	(katun) 13	Ahau

CHRONICLE OF CHICXULUB			
Maya:	Lai	cu xocol	yabil
English:	Here	the count	of the years

This passage (Brinton, 1882:222) is suggestive of the Secondary Series Introductory Glyph.

From the above it is clear that the suggested translations of the hieroglyphs are closely paralleled by passages in the books of Chilam Balam when allowance is made for the different system of enumerating tuns, and to some extent these resemblances strengthen the interpretations proposed.

ADDITIONAL EXAMPLES OF ANTERIOR DATE INDICATORS

Posterior date indicators far outnumber anterior date indicators, because most distance numbers are counted forward. For instance, there are four distance numbers on Stela 3, Piedras Negras, and four on the west side of Stela E, Quirigua.. All eight lead forward, and all are followed by the posterior date indicator. Two posterior date indicators on Altar Q, Copan, are rather unusual in that Landa's *i* element becomes an infix set in the head of the main element.

In order to amplify the material recorded in Thompson (1943), the following examples of anterior date indicators may be noted: Copan, Stela A, glyph block E2b; Copan. Altar U, glyph block 26 (supplying confirmation of the reading offered in Thompson 1935); Quirigua, Stela C, west side, glyph block A9; Quirigua, Stela K, glyph block B6a; Quirigua, Zoomorph G, glyph block A'3 u.h.; Piedras Negras, Stela 12, glyph blocks A16a and D7b; Piedras Negras, Lintel 2, glyph block X3; Aguas Calientes, Stela 1, glyph block D9; and Los Higos, Stela 1, glyph block D13.

In several cases the identification of the indicator confirms readings offered by Morley as doubtful. An exception is supplied by the second distance number on Stela 2, Ixkun. As this distance number, almost surely 1.4.10, is followed by the anterior date indicator, and that in turn by 12 Ahau, the missing date must be restored as:

(9.17.11.4.10	7 Oc 8 Uo)
1.4.10	
(9.17.10.0.0	12 Ahau (8 Pax)

SNAKE OR EEL VARIANT OF THE ANTERIOR DATE INDICATOR

The use of a snake or an eel as a substitute for the more usual anterior date indicator was noted in my previous paper. As the cases in which this variant is used are few and as all occur at Palenque, it is possible to record all of them in the following table.

TABLE 2.1.

Monument	First Date	Distance Number	Second Date	Eel or Snake with	Glyph Block
Stela 1 Temple XVIII Jamb	9.12.6.5.8 3 Lamat (6 Zac)	1.10.1	9.12.4.13.7 1 Manik 10 Pop	1 Manik	A10
Panel of 96 Glyphs	9.17.13.0.7 7 Manik 0 Pax	7	9.17.13.0.0 13 Ahau 13 Muan	13 Ahau	K2
Temple of Inscriptions East Panel	9.8.17.9.0 13 Ahau 18 Mac	6.14	9.8.17.15.14 4 Ix 7 Uo	13 Ahau	M7
Temple of Inscriptions West Panel	9.9.2.4.8 5 Lamat 1 Mol	2.4.8	9.9.0.0.0 3 Ahau 3 Zotz	3 Ahau	E8
Temple of Inscriptions West Panel	9.11.0.0.0 12 Ahau 8 Ceh	6.16.17	9.11.6.16.17 13 Caban 10 Chen	12 Ahau	L8
Temple of Inscriptions West Panel	9.12.0.0.0 10 Ahau 8 Yaxkin	3.6.6	9.12.3.6.6 7 Cimi 18 Ceh	10 Ahau	P5
Temple of Inscriptions West Panel	9.9.13.0.0 3 Ahau 3 Uayeb	17	9.9.13.0.17 7 Caban 15 Pop	3 Ahau	R3
Temple of Inscriptions West Panel	1.0.0.0.0.8 5 Lamat 1 Mol	8	1.0.0.0.0.0 10 Ahau 13 Yaxkin	Tun sign	H8
Del Rio Stones Tableritos B	(9.11.1.12.6) 7 Cimi 4 Xul	1.(12.6)	9.11.0.0.0 12 Ahau 8 Ceh	12 Ahau	A1

Only in the last case is the record uncertain. This is because the starting point of the distance number is on an unrecovered stone. However, yet another stone, belonging to this group of stones of approximately the same size and with a similar glyphic arrangement, which is now in the National Museum of Archaeology in Madrid (Lothrop 1929), carries the date 7 Cimi 4 Xul. One of the possible positions in the Long Count for this floating Calendar Round date is 9.11.1.12.6, which is 1 tun, 12 uinals, and 6 kins after the date recorded on the six-block tablet in Mexico City. The opening glyph of the latter tablet is 1 tun, clearly the end of a distance number. If our assumption is correct, the remainder of the distance number (12 uinals 6 kins) should be on the missing tablet.

With the exception of this dubious reconstruction, every other date where this eel affix occurs is the earlier in time of a pair of dates connected by a distance number.

GENERAL REMARKS

Further investigation fails to confirm the guess that the flame element might indicate a forward count when attached to a day sign. In view of what has been written above, it might represent *ti*, which has the meanings of 'to, from, or on.' For example, the inscription on Temple 22, Copan, opens with a day 5 Lamat to which the flame affix is attached. There follow several glyphs of unknown meaning. "On 5

Lamat such and such a ceremony was performed or God X's influence was dominant" appears a reasonable translation. Where the flame element follows a Secondary Series without a directional counting glyph, the meaning would be 'to.' Parallels to such readings are to be found on page 66 of the Chronicle of Oxkutzcab where occur passages such as "9 Ahau the tun, on 2 Xul" or "9 Kan the year bearer, on 1 Pop."

As a warning against too ready acceptance of the thesis advanced in this paper, it might be noted that among Yucatec names of fish occur *xul* 'skate.' *Xul* is the usual Yucatec word for 'end.' I have given full consideration to the possibilities of this alternative, but have reached the conclusion that this is merely a confusing coincidence.

This paper is directed primarily to the student of Maya epigraphy. Nonspecialists in the Maya area interested in the development of Maya hieroglyphic writing are referred to the most recent discussions of the subject: Long (1935) and Whorf (1935). Whorf (1933) contains a fairly complete bibliography and a good historical summary of the subject by A. M. Tozzer, but in my opinion much of Whorf's text must be read with great reserve.

A summary of the tentative conclusions reached in this paper is omitted in view of the outline of arguments given on [the first two pages].

The fact that the paper is published in the present series is sufficient indication that the case is not considered to have been completely proved.

Cultures and Peoples of the Southeastern Maya Frontier

John M. Longyear III

CONTENTS

- Ulua-Yojoa Polychrome Complex
- Peoples Along the Southeastern Frontier
- Summary

Most linguistic maps of Central America attempt to represent the range and boundaries of peoples at, or shortly after, the Spanish conquest. This is only natural, since most of the information on which the maps are based has been gleaned from accounts written by itinerant Spanish soldiers and priests during the sixteenth century. When these accounts fail us, archaeological remains are commonly used to fix boundaries. This practice, of course, necessitates the assumption that major linguistic groups also form distinct archaeological complexes, an assumption which, I think, we are justified in making, at least in our present state of knowledge. An assumption we cannot always make, however, is that archaeological remains reflect sixteenth-century boundaries. They do not, simply because the great bulk of our digging, especially in the Maya area, has been conducted in sites abandoned long before the conquest. This is especially true of frontier regions, where we most need "contact" material to supplement historical data. Theoretically, archaeology should be of benefit to the linguist and historian in these very areas, as a clearly worked-out sequence of cultures would enable him to trace the movements of peoples, not in space alone, but also in time.

What we now regard as the southeastern frontier of the Maya was established, almost a decade ago.

His line ran just east of the lower Ulua River from the Atlantic coast to northern Lake Yojoa, thence to the Lempa River border of El Salvador by way of Sensenti, and finally down the Lempa to the Pacific. Although he clearly indicated that his "boundary" marked "maximum expansion . . . without regard to period" (Lothrop 1939, Fig. 3), this same line has since become quite generally adopted as the southeastern boundary of the Maya at the time of the conquest. At first this was done with due reservation, and only because no better information was available, but now "Lothrop's Southeastern Frontier" is rapidly approaching cliché status, with danger of its being accepted blindly and with no reservations whatsoever as "one of the things we all know about the Maya."

Considerable archaeological work has been carried on in this frontier section, especially Honduras, in the past decade, and we are fortunate in that some of this investigation has included contact sites as well as the older, classic material. Although the work was done by many people, without any coordinated plan, the results, together with our previous knowledge of the region, should greatly clarify our understanding of what went on in western Honduras and eastern El Salvador during and before the conquest.

THE ULUA-YOJOA POLYCHROME COMPLEX

This term distinguishes a large body of polychrome pottery, collected to date mainly from the banks of the lower Ulua River and the northern end of Lake Yojoa. None of the various attempts at classification of these

wares has been entirely successful, and only one was made on a stratigraphic basis (Strong, Kidder, and Paul 1938). The classification given below is based on shape, and is intended merely to list the most typical forms of the complex, together with the decorative styles especially peculiar to each.

A. Thick-Walled Bowls and Vases.

Form: Bowls with vertical to slightly flaring walls, dimpled bases; cylinder vases with three low, hollow slab feet; both forms characterized by incurving lip (Strong, Kidder, and Paul 1938, Pls. 12b,d,e).

Design: Grotesque birds, quadrupeds, and serpents; rather grotesque humans; textile patterns.

B. Thin-Walled Bowls and Vases.

Form: Bowls with flaring halls, dimpled bases; cylinder vases, usually flat-based, without supports; straight lip (Strong, Kidder, and Paul 1938, Pls. 8a,b, 12e).

Design: Very stylized human processional and "dancing?" figures; rows of stylized heads; interiors with "counters" pendent from lip.

C. Tripod Plates.

Form: Flat plates, supported on three long, hollow cylinder legs (Strong, Kidder, and Paul 1938, Pl. 8e,f).

Design: Intricate serpent patterns.

D. Handled "Bulge" Bowls.

Form: Globular body, usually with sharp shoulder; straight neck; two vertical loop handles attached at neck and shoulder; dimpled base (Strong, Kidder, and Paul 1938, Pl. 13a).

Design: Monkeys, usually highly conventionalized.

Several other shapes occur in this complex, notably "monkey-handled" ollas and tripod dishes but the ones listed above are, I think, the most typical.

Other ceramic artifacts associated with this polychrome pottery include solid and hollow mold-made figurines and whistles in human and animal forms, frying-pan incensarios, stamps, and candeleros. Nonceramic objects are comparatively rare, obsidian blades, drills and scrapers, cylindrical pestles, manos and metates, the last three being made generally of volcanic stone.

Our knowledge of the distribution of these polychrome wares in time is very incomplete. We know they lie above the monochrome and bichrome ceramics of the region in stratigraphic sequence, but no material has yet been found which overlies the polychrome. The complex is at least partially contemporaneous with the last period of occupa-

tion at Copan ending around 9.19.0.0.0 (ca. A.D. 850). This is shown by the occasional fragments of Ulua-Yojoa polychrome which occur in deposits of this date at Copan. Since no sherds of this ware are found in earlier Copan refuse, it is likely that the bulk of the Ulua-Yojoa complex postdates the Maya occupation at Copan. Even so, there must be quite a gap between it and the conquest. Material to fill this gap has not yet been found in stratigraphic relation to the Ulua-Yojoa complex. It does exist, however, as we shall see presently.

Within itself, the complex appears to be fairly constant from earliest to latest deposits. Our only source of information here comes from Strong, Kidder, and Paul's preliminary discussion of stratigraphic digs at Las Flores Bolsa and Santa Rita, on the lower Ulua and Comayagua rivers (1938:39-62). In general they found that realistic designs tended to be concentrated in the lower levels; conventional and geometric motifs, in the upper. Also, thin-walled vessels with "dancing" figures occurred almost exclusively in the lower levels. These distinctions, however, are not very sharp, and some forms certainly continue unchanged throughout the deposits. Although this impression of sameness is one that detailed examination of the sherd material would almost certainly change, for the present we will consider the whole polychrome complex as a unit.

In charting the distribution of the Ulua-Yojoa complex in space (Fig. 2.2), one naturally starts with the lower Ulua valley, where this polychrome pottery was first excavated and from where, owing to frequent subsequent investigations, it is best known. The great Sula plain is formed by the lower Ulua and Chamelecon rivers and the lowest part of the Comayagua River. Wherever excavations have been conducted in this plain, Ulua-Yojoa polychrome pottery has been recovered in abundance, occurring in deposits often reaching a depth of 4 m. The best-known sites are Playa de los Muertos, on the Ulua near Santiago, and Santa Rita, on the lower Comayagua (D. H. Popenoe 1934; Strong, Kidder, and Paul 1938).

Little is known about the extension of the polychrome complex to the west. Only two or three sites on the Chamelecon have been investigated; all lie in the Naco area. At one, Tres Piedras, a moderate amount of Ulua-Yojoa polychrome was recovered (Strong, Kidder, and Paul 1938:35-37), and this must form our westward limit for the present. Almost nothing, likewise, is known about the archaeology of the upper Ulua, Jicatuyo, and Otoro valleys, but the scattered finds so far reported indicate that the Ulua-Yojoa complex penetrated into at least part of this region.

East of the Sula plain, a similar lack of investigation prevails. A single sherd of a thick-walled polychrome vase from Lancetilla (W. and D. H. Popenoe 1931, Fig. 9) is our only evidence of the existence of the complex on the coast. Inland, on the Cuyamapa River, Ulua-Yojoa ceramics are well represented at La Honduras (Stone 1941:55). This site must lie fairly close to the eastern limit of the polychrome pottery, as recent studies have shown that the Aguan valley, just over the divide, was mainly occupied by the Paya in ancient times.

Our knowledge of the Ulua-Yojoa complex increases to the south. The northern end of Lake Yojoa is a noted polychrome center, the principal sites being Los Naranjos, La Ceiba, and Aguacate (Yde 1938; Strong, Kidder, and Paul 1938). Another focus is the high valley around Comayagua and La Paz, where sites such as Yarumela, El Bisquitil, and La de Vaca yield quantities of Ulua-Yojoa sherds (sherd collections in Peabody Museum, Harvard). The complex also appears to extend as far as the Tegucigalpa region, as a number of vessels in collections attest. Further evidence consists of a sherd collection made by Strömsvik near the capital, containing many polychrome specimens of good Ulua-Yojoa type (sherd collection in Peabody Museum, Harvard). Lack of investigation beyond this point compels us to call Tegucigalpa the limit of Ulua-Yojoa polychrome extension in this direction.

South and west of La Paz is a large stretch of archaeologically unexplored territory embracing the mountainous area on both sides of the Honduras-El Salvador border. Near San Miguel, however, is the large site of Quelepa, the source of numerous private ceramic collections. Among them are many examples of Ulua-Yojoa polychrome wares, in particular thick walled bowls and handled "bulge" bowls with monkey designs (Longyear 1944, Pl. IX, 7,8,13,21). West of the Lempa River, on the other hand, these forms appear but rarely, to judge from their sparse occurrence in collections from this area. The presence in eastern El Salvador of polychrome wares other than those of the Ulua-Yojoa complex but coexistent with the latter, is probably a reflection of the distance separating this region from the other centers to the north.

From the information at hand, then, we see that the Ulua-Yojoa complex embraced a considerable area: from the Sula plain on the north to eastern El Salvador on the south, and from Tegucigalpa on the east probably at least to the upper Ulua River on the west. The complex appears confined to river valleys and lakes, doubtless because such locations are logical dwelling-places for sedentary peoples, this holding true in ancient times as it does today.

All hill sites thus far examined in this region have the appearance of easily defended refuges rather than permanent habitations, and were probably occupied in times only briefly antedating the conquest. A possible exception here is Tenampua (D. H. Popenoe 1936; Lothrop, notes in Peabody Museum of Harvard files), which possesses a large number of mounds, including a ball court, and from where polychrome pottery has been reported (Squier, 1869, Fig. 6; D. H. Popenoe 1936, Fig. 2).

PEOPLES ALONG THE SOUTHEASTERN FRONTIER

As noted in the introduction to this paper, the Ulua Valley-Lake Yojoa line has long been assumed to form part of the southeastern boundary of the Maya. In support of this, archaeological evidence purporting to show the existence of Maya culture in this region has been quoted. This evidence may be grouped under four headings: (1) mound and temple plans, (2) masonry, (3) stone carving, and (4) pottery. Let us examine each of these in some detail.

Mound and temple plans. Rectangular mounds, grouped around plazas, have been considered of Maya origin, and the presence of such assemblages in the Ulua-Yojoa region has been cited as proof of Maya occupancy. This type of plan, however, although employed by the Maya, is certainly not peculiar to them alone. The ruins of Los Llanitos, in eastern El Salvador, consist of several rectangular mounds grouped around a definite plaza, yet there is not the slightest supplementary evidence of Maya occupation at this site (Longyear 1944, Fig. 19). Tenampua, the famous hilltop fortress near La Paz, also possesses rectangular mounds and plazas (D. H. Popenoe 1936, Fig. 1), yet it is mentioned as a "typical Lencan ruin" (Lothrop 1939:52) by the same author who proposed the identification of these features with the Maya: The only temple plan so far revealed by excavations in the Ulua valley is that of the "Temple of the Carvings" at Travesia (Stone 1941, Fig. 46). The design has been attributed to Maya influence, but in reality, if we except squared corners, there is nothing Mayoid about this plan. The typical vault is lacking, and the low square benches flanking the open side of the room are distinctly a non-Maya feature.

Masonry. The presence of cut stone masonry in certain ruins of the Ulua-Yojoa region has been attributed to the Maya, in refutation of this one can again cite Los Llanitos, where cut stone masonry occasionally appeared (Longyear 1944, Pl. IV,7). Cut

stones are apparently also found at Naco, a Nahuatl village of conquest date (Strong, Kidder, and Paul 1938:29).

Stone carvings. The carved "stelae" from the northern shore of Lake Yojoa, once thought to be due to Maya influence, are now generally recognized to have other cultural affinities. The finds consist, in the main, of crude anthropomorphic torsos and heads which seem on present evidence to be most closely related to similar sculptures found in Nicaragua and Costa Rica (Yde 1938, Figs. 12–14; Strong, Kidder, and Paul 1938, Pl. 16). The latter are usually attributed to the "Chorotegan" culture, a term which, of late, has fallen into questionable repute. Whether Chorotegan or not, however, the statues are certainly not classical Maya in type. In the entire territory now under discussion, only four sculptures of true Maya type have ever been reported. One is a human head surmounted by a headdress and another is a death's-head. Both are described by Ham (1896) as coming from the upper Choluteca valley (i.e., near Tegucigalpa), but the caption under the illustration of the human head lists the Humuya valley as its finding-place. Ham is sure the death's-head came from Copan, and the illustration indicates a similar place of origin for the other sculpture. Because of the unique character of these finds and the vagueness with which Ham describes their location, it does not seem reasonable to admit them as evidence of Maya penetration into the Comayagua-Tegucigalpa region. It is not improbable, in fact, that these pieces were actually transported from Copan to the Honduran capital sometime during the nineteenth century, a period in which the famous Maya ruins received several visits from scientists and travelers alike. Two similar sculptures, also reported from the upper Choluteca valley and now in the Genoa Museum (Carnegie Institution, Division of Historical Research, photograph file), may have been brought to Tegucigalpa at the same time.

Pottery. The Ulua-Yojoa polychrome pottery has long been considered the most certain evidence of Maya occupation in this region, the specific diagnostics relating to the Maya being the "glyphs" and "Maya-like men" used as decoration. Upon analysis, however, these features lose much of their Mayoid character.

The "glyphs" on Ulua-Yojoa pottery fall, almost without exception, into one of the following categories: (1) stepped scrolls and frets and miscellaneous geometric motifs (Fig. 3.1a–c), (2) textile patterns (Fig. 3.1d,e), (3) highly conventionalized human

heads, on thin-walled vases and bowls (Fig. 3.1f,g), (4) grotesque birds and animals (Fig. 3.1h), and (5) conventionalized animal heads, especially one which appears to be that of a serpent (Fig. 3.1i). These elements are usually found as rim or basal bands on vessels and, as such, parallel the arrangement of glyphs on true Maya pottery. In other respects, however, they bear little, if any, resemblance to, glyphs, for they are concerned almost entirely with purely geometric or naturalistic designs. Very occasionally, nevertheless, characters of true glyph form are found on Ulua-Yojoa pottery (Strong, Kidder, and Paul 1938, Fig. 19). This assemblage, geometric and naturalistic motifs arranged in band form, plus rare glyph like elements themselves, leads me to believe that the Ulua-Yojoa polychrome complex was profoundly influenced by Maya pottery in this regard, but it does not convince me that it was actually manufactured by, or under the direction of, Maya peoples.

The "Maya-like men" on Ulua-Yojoa pottery are also open to question. They may be Maya and, again, they may not, for I know of no diagnostics on ceramics separating the Maya from their neighbors. To judge from their costumes and decoration, the people shown on Central American pottery dressed much alike throughout the area. In physical appearance they are also very similar, but I think it worthy of note that men on Ulua-Yojoa bowls and vases most frequently are equipped with irregular, even pug, noses and high or bulging foreheads as opposed to the aquiline noses and sloping foreheads usually associated with the classical Maya (Fig. 3.1j,k; Strong, Kidder, and Paul 1938, Pl. 1). True Maya pottery in the Ulua-Yojoa area is so rare that it probably arrived there only through trade; I refer especially to certain stamped wares figured by Gordon (1898, Fig. 11) and some stamped and carved sherds found by Stone at Travesia (1941, Figs. 66, 90).

Thus we see that there is very little, if any, Maya in Ulua-Yojoa culture. The ceramic industry, it is true, seems to have come under a good deal of Maya influence, but it really is quite a different complex. This is perhaps shown most clearly by the ease with which sherds of this culture can be separated from those of Maya deposits into which they intrude. Certainly, aside from this one possibility of ceramic influence, none of the other features of the "hierarchic" or ceremonial cult of the Maya ever seems to have reached the Ulua-Yojoa region. If we seek to trace the southeastern boundary of the Maya through archaeological evidence, we must stop at Los Higos on the Chamelecon, this ruin being the farthest-known extension of the stela cult down this valley (Morley 1920:381–90). To the south, in the val-

3.1. Ulua-Yojoa Polychrome pottery designs: *a-d, f, h, i*: from Strong, Kidder, and Paul 1938; *e, g, j, k*: from collections in the Peabody Museum, Harvard.

ley of the Rio Jicatuyo, the Maya may have reached as far as the present boundary of the Department of Copan, for we have Squier's information that the Chorti Maya extended to the valley of Sensenti (1855:385), while near La Union has been found a massive stone macaw head carved in Classic Copan style (Carnegie Institution, Division of Historical Research, photograph file). In El Salvador, Lothrop's setting of the eastern Maya frontier at the Lempa River finds no archaeological conflict to date (Fig. 3.2).

The peoples bordering the Maya on the east in Honduras and El Salvador, according to the consensus of historical accounts, were the Lenca and the Jicaque. At the time of the conquest, the former appear to have occupied eastern El Salvador and to

have extended north in Honduras to the beginning of the Sula plain and the southern part of the present department of Yoro: From here to the Atlantic coast was Jicaque territory. This distribution of peoples, however, probably, occurred only in times immediately surrounding the conquest. There is evidence to show that the picture in preconquest, Classic times was quite different.

Linguistic evidence concerning the Jicaque is vague and frequently contradictory. Since the early chroniclers used the term "Jicaque" to differentiate between the old inhabitants of a region and the later Mexican peoples, it often turns out that they were employing the word to designate Lenca or Paya, not still a third group. This confusion of terms, in fact, prompted Squier to suggest that all the "Jicaque"

3.2. Distribution of peoples along the southeastern Maya frontier during Classic Maya times (ca. A.D. 850).

might be nothing more than Lenca under another name (1855:380). There is only one clear-cut reference to a Jicaque linguistic group in the Sula-Yoro region. This consists of two Jicaque vocabularies, one collected from near San Pedro Sula and the other from

western Yoro, which were compiled and published by Membreño in 1897. Since the language indicated by these wordlists appears to be distinct from that of surrounding groups (Maya, Lenca, Paya, or Mexican), the identity of the Jicaque must be con-

ceded. From linguistic evidence alone, however, we can say only that the Jicaque occupied portions of the Sula plain and western Yoro in relatively recent times. If we add to this the possibility that some, at least, of the historical references to Jicaque are correct, the occupational picture is extended somewhat, both in space and in time. It is up to the archaeologist, however, to furnish proof of these historical accounts.

The Jicaque cannot surely be identified with any archaeological material dating from prequest times. Strong, it is true, considers it "highly probable" that his Bold Geometric type of Ulua polychrome pottery is Jicaque in origin (Strong, Kidder, and Paul 1938:123), but this premise is based on linguistic and historical data which we have already seen cannot be depended upon. Doris Stone has suggested that certain sherds from the Ulua Bichrome deposit at Santa Rita should be classified as "Sula-Jicaque," but her reasons for this are not convincing (1942, footnote 31; as the only basis for comparison between the ancient Ulua Bichrome sherds and the Jicaque pottery of conquest date is that both bear incised decoration, this comparison is hardly acceptable in view of the great disparity in the ages of these two ceramic groups). It appears from recent investigations by Mrs. Stone that most of the Aguan valley was occupied by the Paya in prequest times. If this is true, we have left only a narrow strip of coast land and the Sula plain in which to search for Jicaque remains. Since the Honduras coast in this area has never been examined archaeologically, we cannot discuss it here. In the Sula plain, however, a different situation obtains.

We have already seen from the previous discussion that the Sula plain was occupied in Classic times by a people whose culture embraced the Ulua-Yojoa polychrome pottery complex. This same complex is also found around Lake Yojoa, in the Comayagua-La Paz area, near Tegucigalpa, and south into eastern El Salvador. At the time of the conquest, the Lenca occupied these latter regions, and tradition has also always awarded them to the Lenca in more ancient times. Here we have no indefinite or conflicting statements. If, then, the Lenca were responsible for the Ulua-Yojoa type of ceramics in these upland regions, and if archaeological remains are at all indicative of linguistic areas, I think we are justified in proposing that the Lenca also occupied the Sula plain in polychrome pottery, or Classic, times. In other words, during the late occupation of Copan and the period of Maya extension down the Chamelecon valley and over into the Sensenti region, the Lenca, and only the Lenca, were the immediate eastern neighbors of the Maya, their territory extending in a rather narrow

belt entirely across Central America in Honduras and El Salvador (Fig. 3.2).

What, then, of the Jicaque? Their place in history comes later. The only archaeological finds definitely attributed to the Jicaque are from sites inhabited just before and during the conquest; some of the sites, in fact, are linked to the Jicaque through the medium of early Spanish accounts (Stone 1942). Their remains are widely scattered, being reported from the Lean River on the Atlantic coast, the Cuyamapa valley in western Yoro, Sulaco in southern Yoro, and San Nicolas on the upper Ulua River (Fig. 3.3). During the fifteenth and sixteenth centuries, then, the Jicaque appear to have occupied much, if not all, of the territory awarded them on linguistic maps. This being the case, they must have succeeded two peoples who held this land in earlier, Classic times: the Paya of the Aguan valley in the east and the Lenca of the Sula plain in the west. Lacking further evidence, we must assume for the present that the Jicaque immediately followed these earlier peoples, and that their cultural remains fill the gap hitherto existing between the latest Ulua-Yojoa polychrome pottery deposits and the conquest.

The original homeland of the Jicaque is unknown, but two likely possibilities present themselves. The archaeologically unexplored stretch of Atlantic coast between the Ulua River and Trujillo might have been the spot from where these people later expanded into the Aguan and Ulua valleys. The only other region from which they might logically have come lies to the east and south of this general area.

SUMMARY

Supposing the above reconstruction to be correct, we find there were two major distributions of peoples along the southeastern Maya frontier in ancient times. During the Classic Maya period, the Maya extended to a line which might be drawn from the middle Lempa River through Sensenti, La Union, and Los Higos to an indefinite point on the Atlantic coast. East of this line, the Lenca occupied the lower Ulua and Chamelecon valleys, the highlands of central and southern Honduras, and all of eastern El Salvador. Beyond the Lenca were the Paya, the Choluteca, and probably the Jicaque, among others (Fig. 3.2).

By the time of the Spanish conquest, there had been a considerable rearrangement in this area. The Pipil had taken over most of western El Salvador, compressing the Maya here into a few small enclaves, and also had penetrated into Honduras (Lothrop 1939, Fig. 1; I do not agree, however, with Lothrop's

3.3. Distribution of peoples along the southeastern Maya frontier in the fifteenth century (ca. A.D. 850).

placing of the Pipil east of the Lempa River, an extension which neither history nor archaeology seems to support). To the north, the Jicaque had pushed the Paya out of the Aguan valley and the Lenca from the Sula plain (Fig. 3.3). These reductions in the area

occupied by the Maya and the Lenca at the height of their culture are doubtless connected with the decline of their civilization, these tribes being almost completely shorn of their former power and glory by the time of the Spanish invasion.
